## A Step towards Economy.

**T**HE wastage of petrol by the employment of heavy vehicles when lighter and more economical machines could just as conveniently be used has long been painfully evident to anyone observing the traffic on any important road. Heavy touring cars, involving the time of drivers, have been freely used for the conveyance of single Government officials, and to many unfortunate motorists whose cars or cycles were of real business value, but who are prevented from using them owing to the all-prevailing order for economy, this lack of system has appeared as savouring strongly of injudiciousness. The Government rightly urges economy, so let us see the seeds of it in Government example.

That there is every need for conserving the petrol supplies can be fully appreciated when one contemplates the enormous demands of the Army and munition factories at home, but this demand could be considerably reduced if every opportunity were taken of using economical vehicles on all occasions possible, not only in the Army, but in the various other Government controlled branches.

Naturally the motor cycle affords the cheapest means of locomotion for one person, though its sphere of economical usefulness may not have been realised to the full.

We and our sister journals have dealt so often with this point that it comes as a real refresher to learn that the Petrol Control Committee have already set to work to enforce economy by advocating the employment of motor cycles for solo use. Government servants who hitherto have used cars have received the direct hint that a motor cycle would be adequate for their demands, and their supply of petrol has been fixed accordingly. We hope to see this excellent move followed up with even greater zeal by the new department, for at home the economy and efficiency of the motor cycle and the sidecar outfit are far from being fully utilised.

## Has a Rotary Engine Reciprocating Parts?

**W**E recently published two letters, the first of which stated that in a rotary engine the pistons did not reciprocate, but revolved round a given point, while the second asserted that the rotary engine was a reciprocating engine pure and simple. Both writers were perfectly right from their own point of view, but they looked at the matter from different standpoints. A third writer, whose letter we published last week, explained the apparent anomaly well when he pointed out that the rotary engine was a reciprocating engine in effect only.

For the benefit of our readers, it may be as well to amplify this statement a little. All motion as we can conceive it must be relative. (A man may be said to be sitting still when, as a matter of fact, he, the chair in which he is sitting, and the house in which he is, are all revolving about the axis of the earth at about 600 m.p.h. if he be in the neighbourhood of London, or something like 1,000 m.p.h. at the Equator, as well as being carried round the sun and through space at a very high velocity.) Motion, then, being relative, the movement of the pistons may be considered as being in relation to the cylinders, when it is reciprocating; or in relation to the whole engine, when it is circular, for the pistons revolve about the fixed big end. It is well to note, however, that the movement of the pistons, although in a circular path, is by no means uniform. The speed increases and decreases as in a non-rotating engine, though not to anything like the same extent, and there is no reversal of motion. In the case of an engine having connecting rods equal in length to four times the crank throw, the ratio of the fastest to the slowest speed, while the speed of the engine, of course, remains constant, is as five to three.

A further instalment of letters received since the above was written will be found in this issue.

## IDEAS: Useful and Ingenious.

Sydney R. Jones.

## CARRYING THE LARGE SHIFTING SPANNER.

OF all tools the motor cyclist carries, the large shifting spanner is the one most frequently needed, and this massive piece of furniture is rolled up carefully or otherwise, according to the character of its owner. Its use generally means that the roll has to be spread out on the road or the saddle, causing a waste of time, and a chance of losing other tools when in a hurry.

Convenient ways of carrying the large spanner.

A convenient place to carry a big spanner, which is at the same time quickly accessible, is in a pocket on the inside of the lid of the bag. Some makers have adopted this method, and fit this extra pocket as standard. An alternative method is to use an ordinary cycle tool case and carry it on the handle-bar. Of these ideas the writer thinks the separate carrier better, the pannier bag being usually locked.—DERBY T.T.

## BOWDEN CABLE FOR GAS TUBING.

THE outer part of a Bowden cable, when new and sound, can be used with satisfaction as gas tubing, provided it is of the covered variety. Care

Using Bowden cable as gas tubing.

must be taken not to crack the waterproof covering; but there is no danger of the light being put out by the cable being nipped, as sometimes happens with small rubber tubes. The ends can be attached to the connections by the ever-useful insulating tape.—P.Q., Stockport.

Readers of "The Motor Cycle" are invited to contribute to this page any ideas successfully adapted to their motor cycles. Rough sketches will suffice.

## A SPRING SIDECAR GRID.

EVERYONE who is accustomed to carrying luggage aboard a sidecar has experienced the numerous disadvantages which accompany the practice of attempting to support one's goods on a grid attached to the rigid frame. Not only is the terrific jolting injurious to the goods thus mounted, reducing a good leather suit case into a disreputable wreck in a very short space of time, but if the load be at all weighty very considerable breaking strain is imposed on the members that support it.

The advantages of a spring carrier are, however, so very obvious that there is no need to dwell further on this point,

An improvised luggage grid made from sidecar springs.

and the following simple grid, though not, perhaps, luxuriously sprung, answers the purpose of affording a carrying space which is sufficiently insulated from severe shock to render unnecessary the use of yards of rope to prevent one's gear from slipping, and on which, incidentally, a couple of petrol tins can be mounted without danger of leakage caused by excessive jolting.

The sketch is, of course, self-explanatory. A couple of sidecar springs—the longer the better, though their length must be decided by their stiffness and the load to be carried—are fastened under the chassis frame in the usual manner, their protruding ends carrying the grid or platform. The springs should be given sufficient clearance from the frame by the insertion of packings at their points of attachment, otherwise they will rattle against the frame when progressing over pot-holes, while generally the spring clips at present in use can be utilised to secure them.—S.A., Leeds.

## PETROL SAVING DEVICE.

I HAD always thought a good deal of petrol must have been wasted in consequence of blow-back from the carburettor, and although I have put new springs on the inlet valve I have never really cured my engine of this fault. The running is not affected in any way—it was only the thought of wasting the precious fluid that bothered me.

Extension pipe to air inlet to catch blow back.

Eventually I fixed an extension pipe to the air inlet, and placed a piece of lamp wick along the bottom, and a piece of gauze at the opening. The wick absorbs the petrol as it is blown back by the closing of the valve, and very little of the fuel wasted.—W.P., Glasgow.

## A SIMPLE CUT-OUT.

RETARD the spark fully. Take a piece of clock spring and drill a hole in it, then screw it down under the terminal on the contact breaker. Bend it so as to touch the magneto casing, as

A very simple method of making a cut-out.

shown in the sketch. This is very useful if the exhaust lifter cable breaks. By fully retarding the spark the engine is switched off.—G. F. JONES, Sheffield.

### Shock Absorbers.

“CHINOOK’S” sensible article unaccountably omitted one of the chief functions of a shock-absorber from a technical standpoint.

When a firm sells a machine to an amateur it is, humanly speaking, certain that on many occasions the engine will misfire or be guilty of false starts before it reaches the scrap heap. When its owners essay to start it, it will not infrequently fire once or twice, and then balk with a terrific jar; or it may misfire mildly for a hundred yards or so till it gets into its stride. Again, unless its owner is superhuman, it will from time to time misfire, and be allowed to continue misfiring on the stand or on the road for a little time, while the owner observes its misbehaviour in order to complete his diagnosis. On all these occasions the engine passes on a frightful jar to the transmission, which is more damaged thereby than through a hundred miles of smooth firing under load at medium r.p.m. It is further very probable that when a shock-absorber locks itself solid under such a shock, part of the jar is retransmitted back to the engine, and adds to the decay which the original shock initiated. It is, therefore, in the interests of both maker and user that any cushioning devices employed in the transmission should damp out these stresses as far as possible. The type of absorber, condemned by “Chinook,” which jams up solid after a sixth of a revolution or so, is obviously very ineffective under such circumstances.

### Underlining the Point.

IN our issue of June 21st “Cadet R.F.C.” bears interesting testimony to the oft-repeated theory that incandescent sparking plugs are responsible for 99% of “drying up,” or of the tired feeling which so often develops in an engine when it is driven hard. As he states his case without explaining it, I beg to underline his point in the interests of novices. He had charge of a W.D. Douglas in France, which ran itself to a standstill in half an hour of high speed. After many failures he cured it by filing off the side electrode of each sparking plug, and bending down the centre point till it was within striking distance of the edge of the plug head. Further improvement, though less appreciable, was obtained by fitting copper rain umbrellas under the cable terminals. The cognoscenti will understand the story at sight. May I explain to beginners that the side electrodes could not get rid of the heat imparted to them by successive explosions, consequently they became red hot, and fired the charge. When they were removed the only slender piece of metal capable of accepting more heat than it could conduct away was the central electrode; the rain umbrellas at the outside ends of these electrodes acted as radiating fins, got rid of some of the

heat, and so created a faster circulation of heat up the electrode, away from its tip. Thus the central electrode in its turn was cured of a tendency to get red hot. “Cadet R.F.C.” will soon learn, if he has not already discovered it, that there are modern British plugs which would have cured this engine straight off, and our more intelligent readers will remember that certain racing plugs have no side electrode in the true sense, but in lieu thereof have a slight outward cam-shaped bulge in the ring of their open heads.

### Sideslip.

OUR “Critics” tackled a very thorny subject the other week. The “manufacturer’s” dictum is that 50% of the responsibility for sideslip rests with the designer, and 50% with the rider. If he were comparing the motor cycles of, say, 1903 with those of to-day, his distribution of blame may be roughly accurate. In those days I was a very clumsy and inexperienced rider, and our machines resembled a giraffe with a steam hammer tied round its throat, the rider being comparable to a pigmy seated between the giraffe’s ears and steering it by a four-inch rein. Yet even in those days I managed to correct most of my skids, and those in counties where the treachery of the local grease is still a public byword. But turning to modern days, I would go so far as to say that any decent rider can hold up practically any modern machine on all British grease. If anybody wants to make a simple test of the personal factor, let him take out his machine, deflate his back tyre to a zero pressure, and try to ride the jigger in that condition. There are plenty of riders who would drive a modern machine at legal limit with a flat back tyre for as long as you made it worth their while. I have seen it done over and over again when necessity demanded, chiefly in six day trials, when a puncture occurred near the end of a timed road section, and a stop to repair on the near side of the control implied a loss of marks. On the other hand, the average rider could not cover a mile on the Bath Road with a flat back tyre without wobbling from hedge to hedge, and falling off every now and then. The test illustrates a man’s knack of controlling a machine which is not easily steered and balanced, and I think the illustration is sufficient to prove how much depends on the rider. Nerve, tyres, handle-bars, centre of gravity, steering angle, wheelbase length, even torque, and a smooth drive all help, but a decent rider on a vilely-designed machine will very rarely get unsaddled by a skid, except when he is caught off his guard, whereas a duffer will come a cropper at the faintest excuse on the best machine in the world, but this type of rider is nearly always in trouble of some kind!

# POLICEWOMEN

## WHO

## MOTOR

## CYCLE

By  
ONE OF THEM

WE never dreamt of motor cycling until three months ago. We had only once seen a woman on a motor cycle near Lewes, and we thought her a wonder. We ourselves were content to confine our motor experiences to such steady-going cars as a Singer, a Hillman, or a Ford. Most of the policewomen can manage Fords, as they are the staple car of the munition factory, but Fords need more petrol than motor cycles, and when we made an application for petrol licences for our work we were given the reply which I understand is now universal—*"This officer is recommended to try a motor cycle."* As our need for quick locomotion was increasing as rapidly as the petrol supply seemed decreasing, we determined to take the Petrol Committee's advice seriously and make the experiment.

We now think we owe them a debt of gratitude, for not only are we ensured a "mount" for any emergency and for any distance, but we have entered into a new "sport" more exhilarating and refreshing and exciting than any we have previously gone in for. We all think a ride which presents problems of hill-climbing, traffic threading, or (this must be whispered, for, be it remembered, we are policewomen!) pace-making, beats the joys of skating, skiing, shooting, tennis, boating, or hunting, which we once thought unsurpassable.

Now for a few words about our mounts. None of us had motor cycling friends, so we had to make our own choice. And we had no knowledge whatever, only the memory of a sound—the sound of a purring engine. I expect the grand mechanical readers will smile at the queer way women set about things, but we wanted motor cycles with a sound like the one we remembered. We know nothing of names or makers, but we found our sound twice over, in the Levis and the Enfield, and we have since learnt to recognise the note as the unmistakable purr of the two-stroke engine. We couldn't have two motor cycles each, so we had to choose between them, and chose the Enfield. This was because we were aspiring to the Enfield 3 h.p. twin to go on with, and one of us is going still further to the 6 h.p. twin with a sidecar.

Our work takes us through some rough country and roads, which come near those at the Front for pot-holes. My mileometer registers 1,860, and my colleagues' are not far off. We have tackled most of the Kentish hills, and the little lightweight sings gaily "on top" up such tests as Westerham, Saunderead, Goudhurst, Detling, etc. One of the most difficult hills we have found is the Sevenoaks Hill on the road to Tonbridge. We tried that two or three times, and had always to stop in the middle before we remembered some advice given in

*This officer is recommended  
to try a motor cycle*

Petrol Control Committee.

Official acknowledgment of the economy of the motor cycle. Congratulations to the P.C.C. on this first practical demonstration of a possible solution of the petrol difficulty!

**Policewomen who Motor Cycle.—**

"Hints and Tips to Motor Cyclists," a most helpful friend to the beginner, in which the writer advises the would-be hill-climber with a single gear to smoke a pipe at the foot and have a good think while the engine rests and cools!

We did that—minus the pipe—at the foot of Sevenoaks Hill with the result that our two machines sailed up with a high-note hum, and passed all our brother-wheels on the way. One Flying Corps man with a heavy-looking mount and sidecar, struggling up with an awful noise and rattling valves, was quite cross with us, and said, "There are

pieces of flint or glass forcing their way through the old wound and so damaging the new tube. Another thing we always bear in mind is not to emulate our brethren in mechanical experiments—in other words, not to tinker with our engines. If we are satisfied that our engines are thoroughly cleaned—and with a petrol system such as the Enfield, one's whole comfort depends on scrupulous purification of the carburetter—if the sparking plug seems happy and the pace a gay twenty-five miles an hour with no funking or spitting when hills are reached, *then*, with such conditions, one need enter upon no elaborations of extra air inlet or fancy sparking gaps, etc.

We live in an age which is not easily moved from its nonchalant attitude by even the most unorthodox innovation, but to some it may be an indication of the changing times to learn that we now have motor cycle policewomen inspectors of the munition areas.

women everywhere," but we told him to cheer up, as it was not we, but the lightweights that did the trick, and we vaunted the Ministry of Munitions over the War Office in the matter of mounts—but perhaps that last wasn't fair of us!

**A Lady's Sound Advice.**

Bar a couple of punctures on a road covered with black flints with razor edges, we have not had one trouble. But, as we wasted a lot of time over those punctures, may we pass on what may be a helping hint to our motor cycling sisters—carry a butt-ended inner tube, and if you puncture near the join of your inner tube do not attempt to patch it, but change the tube and do not forget to stick a good patch of canvas inside the outer tyre to prevent small

These little lightweights are extremely sensitive, very docile if gently handled, very easily upset, and most troublesome when once upset. I met a most distressed and grimy young man some weeks back; he was labouring along on a smoking and spitting lightweight which seemed to be oozing oil and smoke at every pore. He looked enviously at our trim and sparkling mounts, and said he was trying a new kind of magneto. It was a very technical description, and it was not what the maker of the cycle had intended him to have. I could not understand his explanation, but I did understand that we were going to have a lovely ride, and that he, poor thing, was in, for a rotten time.

Ah! One word about clothes—a most important subject to us and our sister riders. In our opinion

### Policewomen who Motor Cycle.—

the "eternal feminine" is no good for motor cycling. We were told by our "brethren" that riding in a skirt was "quite comfortable," but we soon proved the contrary. To ride in comfort, to be able to sit down by the roadside and tackle "running repairs" to lessen the contraction of sitting still for a long time, one must be free to jump off or jump on without the restraint which the skirt, however well cut, imposes. In uniform we find top boots and long riding coat give the most "official" effect.

For riding in plain clothes we have the ordinary mackintosh coat, corduroy breeches, boots, and gaiters. The corduroy we have chosen as being durable, warm, yet not too hot or heavy. Messrs. Selfridge have designed us a very comfortable loose cloth cap which entirely covers the hair, keeps out dust, and does not blow off. The usual disclaimer, please, for this last information.

The policewoman must be able to undertake roadside repairs, and the photograph shows a driver of an Enfield two-stroke busy effecting some minor adjustment.

## The Wearing Qualities of All-chain Drive.

### The Experience of a Clyno Owner using Totally Enclosed Chains.

IN the issue of *The Motor Cycle* for June 7th a short article appeared discussing the merits and demerits of the two systems of drive in common use at the present time. In this connection the experience of one who has used an all-chain-driven sidecar between 28,000 and 29,000 miles may be worthy of note. The sidecar in question is a 6 h.p. Clyno 1914 model, which has been directly under our observation for over twelve months. It has recently been dismantled with a view to a complete overhaul, including re-enamelling and plating. By reason of war work occupying all modern factories, the whole of the work, except the plating, had, perforce, to be undertaken at home. Every part has been carefully scrutinised during the dismantling process for defects or signs of wear, and a pleasing fact is revealed that very few replacements have been found necessary.

Regarding the transmission, it was fully expected that new chain sprockets would be required, but the wear was found to be so little that new ones were

quite unnecessary. The photographs show how little the teeth of the sprockets have suffered, the large one being in specially fine condition. The present chain, which is as new, has served for 12,000 miles, and is the production of the Coventry Chain Co., Ltd., the original one supplied with the machine having been accidentally broken.

The whole secret of the splendid wearing qualities of this transmission is that, in addition to the excellent and suitable quality of the materials used, the drive is totally enclosed in oil and dustproof cast aluminium chain cases.

The above facts help to prove that chain drive, under favourable conditions, has almost unlimited wear, and it may be pointed out that the above machine is not fitted with a shock absorbing device, though, of course, the clutch

has been judiciously used. Except at very low top gear speeds, the engine pulls perfectly smoothly. Beyond cleaning out for the purpose of inspection, the gear box, too, was found to require no attention, its condition indeed was magnificent—truly a fine record.

The original chain sprockets of a Clyno outfit which has covered 28,000 miles.

# THE Critic

## Fireside Chats on Motor Cycle Problems

### INVERTED CONTROL LEVERS AND ENCLOSED WIRES

AS usual the Novice kicked off. He said: "I don't know whether you fellows noticed a short article in *The Motor Cycle* last week in which a writer denounces inverted levers and obscured wires as a veritable *bête noire*. If so, what's your opinion? It seems to me that the matter of handle-bar levers is an important problem."

All of them had read the article. The Manufacturer expressed surprise that a writer who appeared normally to have an average share of sound judgment should possess such unusual tastes and depart so entirely from the policy of his paper. "Here, for years past," he pointed out, "we have been striving to obtain neat and unobtrusive controls, then 'Chinook' goes and damns everything!"

"I must say that they struck me as most extraordinary views," the Journalist added. "If the writer under discussion prefers the spiky variety of controls let him have them. There is no need to attempt to divert the minds of others from the obvious and ordinary style of things."

#### Opinions Differ.

The D.R. laid down his pipe, and, with an air of fixed determination, regarded the Journalist and the Manufacturer. "I agree absolutely and unflinchingly with 'Chinook,'" he stated. "I have regarded the inverted lever and the inside wire as a positive menace ever since pedal cycle days. I have had enough of them to last me a lifetime."

"The same here," stated the Novice. "My mechanic charges sixpence a time for repairing an ordinary outside wire, but he charges one-and-six a time for repairing the inside wires of my machine. That conveys some idea as to the respective accessibility of the two methods."

The Manufacturer agreed that the outside controls were perhaps a little more accessible than the inside variety, but qualified his statement by adding that this was because so few riders knew how to handle the inside wire. "A rider with any sense objects to a multitude of spiky levers," he added, "and to converting his handle-bars into a veritable *chevaux de frise*."

"He's got to have the levers anyway," retorted the D.R., "and I fail to see why, because they are outside, they should be unduly spiky and aggressive. True that the average clutch lever sticks out in a nasty way, but there is positively no reason why it should. The amount of lift need not be anything like that allowed by these wide-angle levers,

which are difficult to get hold of. They would be more comfortable and give better leverage if designed on the lines of the ordinary inverted lever—that is, the lever normally lying almost parallel with the bar."

#### Lubrication and Weatherproofness.

"You cannot have outside levers and outside wires without crowding up your bars," the Manufacturer pointed out. "There is nothing neat about the arrangement, and the sight of such a jumble of levers is enough to frighten a novice off any one make of machine. Besides all this, I consider the outside lever dangerous, as if you ran into anyone with a machine so fitted the lever could very easily inflict a fatal wound. As for the wires, an enclosed wire is neat, out of the way, and protected from damage."

"Certainly, and if your outside lever must protrude from the bars almost at right angles, it is dangerous," snorted the Novice; "but surely that is not a necessary point in their design?"

"Another point," broke in the D.R. "Talking about danger, there is this point to consider. We must have three Bowden levers—brake, exhaust lifter, and clutch—so that one of them (the clutch) must be on the outside. There is, therefore, a very real danger of the clutch being rendered suddenly inoperative should it shift its position so that it fouls the inverted control. On one or two occasions I have very nearly collided with lorries through this happening, and once, indeed, I got my hand imprisoned between the open control and the inverted. Very nice, I can tell you!"

"It is hardly fair to blame the inverted lever because the open control may slip out of position," said the Journalist. "Moreover, can you tell me why so many leading makers choose the inverted lever and the inside control?"

"Yes," answered the D.R.; "because it is neater, and looks clean and simple."

"Also for protection," answered the Journalist. "By having the wires inside you protect them from damage and from the weather."

"Here, again, I do not agree," replied the D.R. "As regards damage, the only point where the wires need protection is in passing through the spring forks, and the inside variety has no more protection at this point than the outside. In fact, the outside wires are more easily guided out of harm's way, for by having plenty of slack you can arrange them in a wide curve quite clear of the forks, and, what is more to the point, quite free from kinks."

"Hear, hear!" muttered the Novice. "Then, as concerns weatherproofness, I fail to see the object of concealing only one foot of the cable throughout its entire length. It merely means that you cannot oil the end of the wire where oil is most needed. I have known moisture to follow the trend of the wire into the bars, with the result that rust sets in along the obscured length. Next, one or two strands break, till, after working stiffly for some time, the wire finally gives out. Thus the inside wire is more likely to break than the outside, and it is more difficult to mend when it *does* break."

"You are certainly trying to make the best of your case," observed the Journalist, "but your remarks contradict themselves. If moisture will follow the trend of the wire, oil will most certainly do the same, and, what is more, if the oil is given the first chance, it will to a large extent prevent the water from following. My business hack has inside wires. Only once has one of them broken during three years of all-weather riding; then it was a matter of only a few minutes to slip in a new wire."

#### Accessibility.

"Just my point," the Manufacturer backed him up. "Inside wires and inverted controls normally give so little trouble that it is not worth while putting up with the ugliness and clumsiness of all outside controls to eliminate it. How often do you experience wire troubles in these days? Not till the machine has seen two seasons' use."

"Exactly so," agreed the D.R. "It is because the inverted control has to be taken adrift comparatively seldom that one can confidently expect to find it permanently rusted into the bars when finally it *does* have to come out. That's when the fun begins. The day inevitably comes when the sockets have to come out. Either you want to change the bars, or to put new cones in the steering head, or possibly you want to reverse the controls. Any of these things can be done in a few minutes if all the controls are outside. If they are inside, it is a full evening's work—if all goes well."

"I deny this entirely," said the Journalist. "You unscrew and detach your handle-bar lever, I slip the exhaust lifter wire from the engine, and allow the wire to come away with the handle-bars—a matter of a moment only, and it can be done without removing screws. The same thing can be done with the front brake."

"What are your two inverted controls?" queried the Manufacturer. "The

### The Critics.—

exhaust valve lifter and the brake, both of which you use so seldom that the wires last indefinitely. In these days we use our carburettor controls instead of the exhaust valve."

### How Wires are Broken.

The D.R. thumped the table. "Look here," he said; "exhaust valve wires are more likely to be broken to-day than in the days when they were used as controls, and for this reason—because we use them in conjunction with the kick starter when the engine is stationary. This means that the wire is often used to haul up the valve against the spring, whereas, when the engine is turning over, the tappet lifts the valve, and the wire has merely to anchor it up. It is in starting that the wires are generally broken by people hauling on them, and you cannot deny that the outside variety are infinitely easier to repair than the inside."

The Journalist appeared thoughtful. "There are yet two other reasons why I prefer the inverted," he stated. "They give you something to hold on, so as to rest your wrists, and, besides making the handle-bars neater, they render them much easier to clean. You talk about

protection—well, the point at which protection is most needed is on the bars themselves, where the cables are apt to foul the sharp edges of the horn and lamp brackets. If the bars are clear of outside wires, there is no trouble in arranging other fittings, whereas if the whole thing is tangled up with wires, the fittings and the wires all get in each other's way, and after a week or two one finds the waterproof covering of the wires cut through—probably in three or four places."

"There is certainly something in your latter argument," agreed the Novice, "but your first is weak, because you can buy buffalo horn grips which give you just as comfortable a hook to hang on to."

"As comfortable perhaps, but not so strong," put in the Journalist.

"And there is yet another point," concluded the D.R. "What about weakening the handle-bars by drilling them?"

### A Weak Point.

"Drilling is not necessary when bars are designed for inside controls," argued the Manufacturer. "What, when you leave your machine at a garage or at some other place—stacked with other machines

—as you so often have to do? The garage boy packs another machine side by side with yours, and in drawing it back on to its stand, one of its levers catches one of your outside wires, snatching round the bars and probably permanently kinking the wire."

"They don't catch in mine," retorted the D.R., "because I keep them neatly clipped to the bars—not slopping about in all directions. My bars are as neat as any you can see."

### Neatness Counts.

"Still, it is absurd to argue that an exposed cable is no more susceptible to damage than an unexposed," said the Manufacturer. "On one side we have incomparable neatness and protection. On the other we have accessibility. The rider who prefers all outside wires can get them. It is not for the manufacturer to choose a slovenly method in preference to a tidy one. The inverted lever is commendable because the little extra trouble it may occasionally give is fully warranted by its neatness and simplicity."

"And because," sighed the Novice, "it teaches patience, perseverance, and control of one's temper. Every man to his own choice."

## Another One-piece Sidecar Outfit.

A DESIGN FROM SOUTH AFRICA.

THE arrangement here illustrated hails from Natal, and appears to be another effort in the direction of the sidecar outfit built as a one-piece structure. The illustration is self-explanatory, but a brief description will perhaps prevent the reader from misconception.

The framework may be said to consist of three parts—the main rigid structure, which carries the engine, passengers, etc., and the two shaded members, which function respectively to support the two rear wheels. These shaded members, it will be seen, consist of swing brackets, at one end of which the wheel is mounted, while the other end is pivoted to the main frame, so that they can swing on their pivots in a vertical plane independently of the main frame. In the case of the driving wheel, two leaf springs, one on either side of the wheel, are placed between

A patented design in which the motor cycle and sidecar frame are one structure.

the unsprung brackets and the main frame, so that the weight of the main frame is supported on these springs; while in the case of the sidecar wheel one spring functions in the same manner. Thus we have all three wheels of the

outfit independently sprung, while the main structure consists of one rigid unit.

There are perhaps numerous points in this design which indicate weakness. In the first place it is not quite clear why the inventor chooses to mount his heavy springs as unsprung weight when they might just as conveniently travel as sprung weight. The driving wheel bracket appears at first glance to be efficient, but while its strength in one direction is in excess of requirements, the vertical rigidity of the wheel is almost entirely dependent on the short length of tube extending parallel with the spindle and between the two pivots. Any tendency on the part of the wheel to move out of the vertical would impose an enormous bending stress on this short tube member. There are other points, such as complicated brazed junction lugs, while the construction is not on scientific lines.

## Attachments to the Handle-bars.

VERY often considerable difficulty is experienced in inducing such articles as the horn or controls to retain their upright position on the polished bars, a strip of thin leather being the remedy generally resorted to prevent the usual slip. But even with the leather packing a certain amount of creeping generally takes place, and soon an all-round straightening up is necessary. In order to save oneself the trouble

and irritation which the insecure attachment of the handle-bar accessories so often occasions, it is a good plan to smear the piece of leather used on both sides with seccotine. It will then hold firmly to the polished surface; and an attachment made in this way, and pulled up tightly ere the seccotine sets, very seldom needs further attention. Probably one of the cements which are impervious to moisture, and which are made specially

for such jobs, would prove better than seccotine, which, however, I have found to answer well. Where a little scratching does not matter, a powerful grip can be obtained by folding a strip of emery cloth round the member clasped, tightening the clip on to the emery. This tip often proved valuable in the days when engines were merely clipped to a single frame member, round which they were prone to swivel.—S.B.

# SINGLE LEVER CARBURETTERS.

A Practical Test of Three Types. The Results obtained on a Single, a Twin, and a Four-cylinder Engine.

THE rudiments of carburation are little known to the average motor cyclist for the reason that the majority of machines are fitted with two lever carburetters, while the car type is in its infancy as far as motor cycles are concerned owing to its high price and the time taken in tuning. Yet a simplified method of control for the benefit of novices is urged in many quarters, and a single lever carburetter would help to popularise motor cycles. The writer has recently carried out experiments with the Claudel-Hobson, the Zenith, and the S.U. on singles, twins, and four-cylinder machines with most interesting and instructive results. Some notes on the design and a record of the results achieved are appended.

## The S.U.

The S.U. carburetter is extremely sound in principle, for both the air and petrol are governed by the suction of the engine. It was found, however, that on the singles it was not quite a success, as the intermittent suction had a detrimental effect on the air piston; the engine was slow to pick up and had no reserve power at slow speeds, although the results were good above 25 m.p.h. The twin was able to tick round in low gear so slowly that the machine was hard to balance as a solo mount, while the acceleration showed a marked improvement over that obtained on the singles; there was plenty of power, and consumption was quite good.

When fitted to the four-cylinder the result was still further improved, as might have been expected; slow running was excellent, both under load and with free engine; the acceleration was rapid and good power was

obtained, especially when labouring up a hill on top gear. The petrol consumption worked out rather higher than on the twin, but that must be expected on a four-cylinder of the same capacity; what was

noticed, however, was a marked improvement with regard to drying up—which was felt at times on the twin, especially in quick throttle opening. Altogether the result was particularly good on the last machine, which shows that this carburetter requires an even suction to stop fluctuations of the air piston.

The principle of the automatically variable jet is worthy of great praise, and the only thing which is missing is a stop to prevent the throttle closing so as to ensure slow running, but a fitment was easily made

which proved very successful. A hot air pipe is absolutely essential to obtain good results.

## The Claudel-Hobson.

The Claudel-Hobson was the next on test. Fitting was made rather difficult by the vertical opening but was successfully performed, being simplified to some extent by the semi-universal joint for the petrol pipe.

This carburetter is quite different from the usual type of single lever. The air is governed by the slots in the throttle, and the jet is a great help to vaporisation owing to the unconventional design. Simplicity is the hall-mark, and there is only one moving part, viz., the throttle. No pilot jet or by-pass is fitted, but slow running is accomplished by a small stop screw situated in the throttle housing which prevents the throttle from closing.

The suitability of this carburetter for practically any machine is noteworthy, while for a twin the result is beyond

The S.U. carburetter.

Claudel-Hobson carburetter in part section.

### Single Lever Carburetters.—

praise. A remarkably slow tick-over and a violent acceleration are its prominent features, both on a twin and four-cylinder engine.

In adjusting, it is necessary to remember the variable choke screw, as this more than all governs the ultimate running, and when tuning for the best results it is advisable to use a slightly larger jet with the choke screw nearly out, as this gives a larger reserve of power when the throttle is nearly fully open. The absolute necessity of fitting a hot air intake is apparent, for the carburetter is not at its best until well warmed up, but a few hundred yards in bottom gear will do this and smooth running will result. In conclusion, it must be borne in mind that the carburetter must not be too big for the engine, as, in that case, the results may be disappointing. A 16 mm. choke is quite big enough for a 5 h.p. twin or a 2 $\frac{3}{4}$  h.p. single.

### Zenith.

The Zenith carburetter has a great name in the car world. It strikes a motor cyclist as being somewhat complicated in design owing to the compensating jet for slow running, but the principle can be quickly mastered. In test the horizontal type was not a success, but the vertical model is perfect owing to the ease with which a hot air pipe may be fitted to the cylinder fins. The effect was good all round on the single—slow running, moderate acceleration, and plenty of power, while the consumption was low. The twin gave similar results, but the even suction was accompanied by better acceleration. The fitting on the four-cylinder necessitated an elbow, but there was a marked improvement over the two-lever carburetter,

The Zenith carburetter, showing compensating jet at right.

and the r.p.m. could almost be counted when running on a properly adjusted pilot jet, while a speed of more than the legal limit was obtained, enabling hills to be rushed "on top" with a heavy sidecar. The "pick up" was surprising, and it was possible to accelerate from a slow crawl in traffic to well over 20 m.p.h. in the matter of a few yards. The consumption was very low considering the heavy weight of the combination.

In fine, the carburetter is ideal for heavy touring on practically any make of machine. It is extremely well made, and every detail has had great attention paid to it, while a large stock of fittings, such as elbow bends and jets, are kept in stock by the makers, who will carry out adjustments to any purchaser's machine and give advice as to the size of jets, chokes, and compensators needed.

### Impressions.

When the good old times of peace come again with the trials and speed events, the single-lever carburetter will, *me judice*, become more widely used than at present. for our American cousins have not been slow to see the utility and superior excellence of this instrument, and with its twist grip controls the automatic carburetter is ideal. We get nearer the car every day with our dynamo lighting sets, detachable wheels, comfortable sidecars, and reliable engines. Why, then, not go one further by fitting a car type of carburetter which allows a slow tick-over, a fierce and rapid acceleration, which so far has been somewhat of a myth. Practically the design of the two-lever carburetter has not changed during the past six years, while the engine and transmission have forged ahead with wonderful rapidity. D.W.

## The Next A.C.U. Trial.

PEACE rumours have not of late been persistent, yet to the ardent motor cyclist the very thought that the war must some day end brings anticipations of the next Six Days Trial. I suppose its most prominent feature will be the many missing faces of those once formidable in such events, and now resting beneath an alien and blood-stained sod. When we have paid silent tribute to these gallant memories, our mechanical instincts will reassert themselves, and we shall find much that is new to interest us. The baby two-stroke should be there in fleets, and I question whether it will stand up as well under a week's stern testing as some of its devotees expect. Then the big multi-cylinder two-strokes will make their competition *début*, so far as serious work is concerned. I wonder how many of them will venture to turn out with sidecars attached. If any of them can get through a week of freak hills under double load, there will be

"some" boom in them. Possibly the lilliputian four-stroke may figure in the list; and, above all, the spring frames will attract universal interest wherever the trial goes. I don't suppose the trial will spell huge enjoyment for the participants, whether riders or officials. The function of a trial is to prove to the public the general level of efficiency, and to differentiate between those machines which touch a reasonable level. The first function will be fulfilled by the vast bulk of the machines ascending all the test hills and scoring practically full reliability marks. The necessity of emphasising the second function will burden the week with a long series of scientific tests, acceleration, and the like, which will entail a lot of hanging about and anxiety for the competitors and officials. One really regrets the old "all-in" trials, where it was simply a matter of finishing somehow; it is a pity that the growing perfection of our mounts has bidden those days an inevitable farewell. ROAD RIDER.

## ALUMINIUM AND AIR-COOLING.

Some Historical Facts concerning its Adaptation to Air-cooled Motor Cycle Engines.

**"The Motor Cycle's" Discovery of Patents dated 1897 and 1898 covering the Use of Aluminium for Cooling Purposes.**

**A**N informative article dealing with the subject of the uses of aluminium alloy in air-cooled engines appeared in *The Motor Cycle* of June 21st. The several alternatives were illustrated, and their advantages and disadvantages discussed by Mr. Georges Funck, A.M.I.A.E., with whom we had collaborated in the preparation of the article. Our particular interest in the use of aluminium alloy for air-cooled motor cycle engines has been made very clear on a number of occasions, and our investigations and study of the subject have led us to a discovery. It is generally supposed that the use of aluminium alloy in air-cooled engines is something quite new, but, as a matter of fact, the reverse is the case, the patent files proving once again the old adage that "there is nothing new under the sun."

### Forestalled!

It was mentioned in the previous article that Mr. H. H. Wardle (whose provisional patent of 1914 we referred to as well as his experiments with an aluminium encased cylinder on a Triumph motor bicycle) did not complete his patent, and, being interested in this early recognition of the possibilities for the aluminium alloy cylinder—particularly in view of latter-day developments—we sought out Mr. Wardle at the Reliance Foundry, Coventry, in order to hear his experiences and impressions of the use of aluminium on a motor bicycle engine. Incidentally, we enquired why his patent was not proceeded with, since war-time developments on aeroplane engines have demonstrated that such a patent might have been worth annually many thousands of pounds. Mr. Wardle was good enough to show us the original cylinder casting he had tested on his Triumph motor cycle, and it is a very neat job, though considerable difficulty was experienced in the casting process, due to the

projecting valve chambers. The patterns, indeed, cost £30 to produce. Mr. Wardle confided to us that he did not go ahead with his patent for the very good reason that he was advised by his patent agent that a strong patent was impossible, as a patent already existed, dated 1898, covering "the use of a metal, for cooling purposes, having a higher conductivity than the metal of which the tube or cylinder itself is composed." Of this, more anon.

### The Usual Cold Reception

Before the investigation was complete, however, Mr. Wardle offered his patent to different motor cycle firms, who, not knowing of the snag that Mr. Wardle was later to encounter, sad to relate, gave it a cold reception, and eventually the outbreak of war put an end to Mr. Wardle's further efforts. When the patent search revealed a prior claim, his provisional patent was allowed to lapse. As to his experiences with a  $3\frac{1}{2}$  h.p. Triumph, Mr. Wardle spoke highly of the improved results obtained. The cooling effect of the aluminium jacket was so pronounced that, when running along the road, it was easily possible to hold one's hand on the fins. He proved, too, the remarkable economy effected in the use of lubricating oil, one-third the amount formerly used being found sufficient. Compression was maintained indefinitely, the valves and their seatings keeping in good condition and hardly ever requiring attention. Another significant fact was that, when the cylinder was dismantled for the removal of carbon, the deposit was found to be wet as in the case of water-cooled engines and easily removable. We illustrate Mr. Wardle's Triumph engine with its aluminium encased cylinder. The cylinder and crank case were polished, giving a very pleasing result, the engine being not only neater in appearance but lighter look-

**ALMOST AN ALUMINIUM ENGINE.**

The cylinder of this motor cycle engine has a covering of aluminium, including the cooling fins. It is polished to match the crank case.

### Aluminium and Air-cooling.—

ing, as well as lighter in reality. In his original experiment Mr. Wardle took an ordinary Triumph cylinder and chipped off the fins, so that he had a plain barrel. This barrel was utilised in the casting process as the core, whilst a special wood pattern was made and the aluminium run round to form fins to the depth of the original cast iron fins. With a two-stroke engine the casting would not present such real difficulties, and in view of the higher temperatures generated by two-stroke engines, a cylinder of the type in question should prove particularly attractive to designers anxious to obtain the utmost efficiency. Now, the more usual course in aeroplane engine construction is to provide an aluminium cylinder shrunk over a thin cast iron or steel liner. Sometimes the aluminium casing envelops only the barrel of the cylinder, *i.e.*, a detachable head being used. In other cases the entire cylinder casing is composed of aluminium, shrunk into position on the liner.

### Activities Twenty Years Ago.

To revert to the earliest efforts in this connection, investigations undertaken by *The Motor Cycle* enable us to announce that one of the first, if not the first, to grasp the possibilities of the use of a metal of high heat conductivity was Robert Ayton, of Coventry, who on August 12th, 1898, lodged an application for a patent, and the complete specification was accepted on 12th October, 1899—nearly twenty years ago. In the early days of motor cycles we knew Mr. Ayton very well as an engineer and a motor cyclist, though we did not discover until we had made this search that the patent referred to was one of his many inventions. Since 1914 Mr. Ayton has been in the R.N.A.S., and is now a chief petty officer.

R. Ayton on the motor cycle he constructed in 1907 for the T.T. race. The engine is a Riley. Mr. Ayton won the first private owner's prize in the T.T.

We regret to say that he saw no direct benefit from the patent. He was too much in advance of the times, and suffered as many other far-sighted men have done. It is galling to think that a patent expires automatically at the end of fourteen years, when during that period no one recognises the value of the patent, and yet subsequently the scheme covered by the

patent specification becomes common practice. One is tempted to ejaculate, "Wake up, England!" But Mr. Ayton's patent was a strong one, and exceptionally lucid in expression.

In view of its particular interest to all air-cooled engine users and designers, we quote the wording of the original specification, and reproduce the drawing accompanying it. Note that the address named is not now correct.

### IMPROVEMENTS IN OR RELATING TO RADIATING DEVICES FOR HEATING OR COOLING PURPOSES.

I, Robert Charles Ayton, of 5, Richmond Terrace, Cox Street, Coventry, in the County of Warwick, engineer, do hereby declare the nature of this invention and in what manner the same is to be performed to be particularly described and ascertained in and by the following statement:

This invention relates to radiating devices for heating or cooling purposes.

According to this invention I provide the tube, cylinder, or other body from which heat is to be radiated, with a partial or total covering constructed of a metal having a higher conductivity than the metal of which the tube or cylinder itself is composed. Thus in applying the invention to the cylinder of an internal combustion engine, the cylinder may be provided with a conductive covering or with wings or gills constructed of aluminium, silver, or some alloy of these or other metals, whose heat conductivity is considerably greater than that of the iron or steel of which the cylinder is composed.

The conductive covering may be plain, corrugated, or provided with wings or gills, or the latter may be applied to the cylinder, tube, or other body separately or in groups, or the covering may be given any shape suitable for increasing the radiating surface of the tube or cylinder which is presented to the air or surrounding fluid.

It is, of course, necessary that the conductive covering should be applied to the radiating body in such a way as to ensure intimate contact between the metals of which the body and covering are composed.

The accompanying drawing illustrates in longitudinal section a portion of the cylinder of an internal combustion engine with radiating gills fitted in accordance with this invention.

The gills A, which may be of any convenient form, are made of some metal having a higher conductivity than the metal of which the cylinder B is composed. In order to ensure intimate contact between the metals it is preferable to cast the gills in position upon the cylinder, but other methods of placing the latter in position may be employed, thus, for example, the exterior of the cylinder may be tapered and the interior of the radiating covering being correspondingly shaped, or the radiating covering may be simply shrunk into place, the method of applying the covering varying in accordance with the body to which it is to be applied.

It will be understood that the invention is equally applicable in the construction of condenser tubes or radiators such as are employed for heating or cooling purposes.

### A MASTER PATENT?

**Aluminium and Air-cooling.—**

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:

1. The combination with a body radiating heat of a conductive covering formed of a metal having a higher conductivity than the metal of which the radiating body is composed.

2. The combination with a body radiating heat of radiating gills formed of a metal having a higher conductivity than the metal of which the radiating body is composed.

3. The combination with a body radiating heat of a conductive covering formed of a metal having a higher conductivity than the metal of which the body is composed and cast in position upon the body.

Dated this 12th day of May, 1899.

BOULT AND WADE,

Agents for the Applicant.

**Establishing the Original Patentee.**

Our conviction that aluminium will enter largely into the construction of petrol engines of the future has been re-echoed throughout the world. Its use promises to solve many of the outstanding difficulties to which motor cycles are commonly subject, such as:

- (1.) Rapid formation of carbon deposits.
- (2.) Knocking due to excessive heating.

- (3.) Short life of valves and seating.
- (4.) Excessive consumption of lubricating oil.
- (5.) Rattling in two-strokes.
- (6.) Sticking piston rings.

In investigating the subject of the employment of aluminium for air-cooled engines, our sole object was to determine the originator, so that praise could be offered where it is due. It has been our pleasure to offer hearty congratulations to our friend, Robert Ayton, upon his clear foresight, and sympathy that his patent should have expired before the advantages his system offered were generally appreciated. We have received from Mr. Ayton in reply a most interesting letter, extracts from which we hope to publish in our next issue. Incidentally Mr. Ayton has sent for perusal a copy of the only patent specification prior to his own of which he is aware, in which the use of aluminium is referred to as a material for cylinder cooling fins. This is a specification by E. J. Pennington, a pioneer of the motor industry. It is clear, however, that Pennington only suggested aluminium as a possible material on account of its ductility. This patent will be dealt with in more detail in the next instalment.

On Saturday the "Old Timers" of the cycling and motor cycle world met at Stonebridge, arriving on all manner of machines, the ancient crocks causing much amusement and interest. Our photograph shows some of the Coventry contingent starting. Left to right: Sam Wright, on the first Humber G.O. ever made; Mr. J. W. Maude (Centaur Co.) on an "ordinary"; and Mr. V. A. Holroyd (Rudge-Whitworth, Ltd.), a cyclist and a motor cyclist.

**AMERICAN MILITARY MOTOR CYCLES STANDARDISED.**

TO standardise the American motor cycle for war work was the main purpose of a meeting of American motor cycle engineers held recently at the headquarters of the Society of Automobile Engineers, New York.

No one American factory can turn out a sufficient number of motor cycles to supply the army America is raising, and, therefore, it is necessary that steps be taken to standardise the parts of the various machines used. It was urged that the S.A.E. screw

thread be standardised, and that standard gauges for belts be adopted forthwith, and be put into immediate operation on machines built for the new army.

Committees were formed to work out suitable standards for wheel rims, tyres, spokes, handles, hubs, chain sprockets, handle-bars, and controls generally. Motor cycle parts, such as pistons and connecting rods, are to be standardised so far as their varying designs permit, and this also applies to chain guards, mudguards, tanks, filler caps, etc.

## A.S.C. (M.T.) Motor Cyclist and Speed Permit.

An A.S.C. (M.T.) motor cyclist, Cpl. Sutcliffe, was stated to have no permit to travel at more than 10 m.p.h. He had to pay 30s. for exceeding this speed on the London Road, Bromley.

## The Red Cross "Draw."

Tickets issued in connection with the "draw" for a lightweight motor cycle arranged by the British Red Cross Society, Newcastle-under-Lyme, totalled 106,000 at the end of last week. The secretary has traced the sale of 8,800 tickets through *The Motor-Cycle*.

## Lady Motor Cyclist, Officer, and Special.

Eileen Manwell was charged at Bromley with driving a motor cycle without a light. Special Constable Palmer, in evidence, said when he asked for her licence, an officer in the sidecar said she need not produce it as he was not in uniform. He also tried to prevent him from taking the numbers. A double fine, 20s., was imposed on the lady.

## New Petrol Control Department.

The Board of Trade has announced that the duties hitherto performed by the Petrol Control Committee are now to be undertaken by a Petrol Control Department of the Board of Trade. Sir Evan Jones, Bt., M.I.C.E., is to be Controller of the new department, Mr. P. G. L. Webb, deputy Controller, and Mr. H. W. Cole, Chief Clerk.

## Maintaining 438 Miles per Day on a Four-cylinder.

Recently Alan T. Bedell, a well-known American rider, rode across the continent on a 1917 four-cylinder Henderson in 7 days 16 hours and 16 minutes. Bedell started with a military message from Los Angeles, California, and duly delivered it to General Bell at Governor's Island, incidentally reducing the Transcontinental record by 3 days 18 hours 54 minutes. Rough and trackless country was negotiated, yet Bedell managed to maintain the extraordinary daily mileage of 438. No mechanical troubles were experienced, and the big four-cylinder finished the trip ticking over perfectly sweetly. And yet one reads so often that the additional complication of the "four" renders it impracticable!

## Messrs. Brown Bros.' Report.

The twentieth annual report of Messrs. Brown Bros., Ltd., shows that £40,715 profit was made in the year ended 1916. A dividend of 7½% (2½% interim dividend already paid), tax free, was declared on the ordinary shares, and bonus 2½% (tax free). £25,781 was carried forward to the next account.

## Bent Number Plate—a Conviction.

An Orpington motor cycle agent has been fined for using a motor cycle with a bent rear number plate. He pleaded ignorance of the regulation. Are front plates shaped to the curvature of the guard illegal?

## To get you Home.

The A.C.U. is now issuing vouchers in connection with its "get you home" scheme, which should be highly appreciated in these days of petrol shortage and of old corks. The idea is that a member can, in the event of a breakdown, obtain assistance and secure conveyance to a railway station or to his destination—if it lies within a distance of twenty miles. No provision is made for the imposter who rides deliberately out into the country till his petrol gives out, on the strength of obtaining a gratis ride home at the expense of the Union.

## SPECIAL FEATURES.

**POLICEWOMEN WHO MOTOR CYCLE.**  
SINGLE LEVER CARBURETTORS.  
ALUMINIUM AND AIR-COOLING.

## A Gigantic Blotting Pad.

Coventry is an absorbing city in these days of munitions. The pavements are not wide enough for the populace, with the result that the latter absorbs the road as its personal property. When one leaves small change on the table for the waiter, it is absorbed ere that gentleman's wide-awake eye discovers it. He in turn will tell you that the Cerebos salt cellars are absorbed wholesale, "owing to the people who come here who never used to have the money." Some of the munition workers are out to do themselves well.

## Alteration of Title.

The title of the Electric Ignition Co. (1913), Ltd., has been altered, by permission of the Board of Trade, to E.I.C. Magnetos, Ltd. The registered trademark, "E.I.C.," has naturally attained some reputation, not only on account of the quality of the goods turned out by this firm, but on account of the excellent treatment their customers have received, and therefore, for the sake of brevity, it has been decided to adopt these letters as the business title of the firm.

## WHICH DO YOU PREFER?

Types of single track machines at the Midland "Old Timers" meeting at Stonebridge last Saturday.

**The National War Funds.**

At the week-end the principal war funds stood as follow:

The National Relief Fund (distributed £3,618,622) .. ..	£6,201,086	0	0
British Red Cross Fund .. ..	7,013,694	16	3
Tobacco Fund .. ..	131,936	0	0

**A Cut-out Demagnetises a Magneto.**

A talented electrician has proved to a member of our staff, by experiment, that the use of a magneto cut-out very gradually demagnetises the magnets. The proof obtained was first by testing the voltage given off by the primary circuit, then running the magneto at a good speed for a few minutes with the cut-out in action, i.e., short-circuiting the primary circuit. When the voltage was tested after the shorting it was found to have dropped somewhat, but after remagnetising showed its former reading upon test.

**The Crank Case Release.**

Many makers are not quite so considerate as they might be as regards the type of crank case release they employ and the position in which they place it. More often than not it deposits oil over the inaccessible and uncleanable nooks; while the type commonly utilised to keep the front chain lubricated, and fitted with an extension pipe for that purpose, is, unless the chain be totally enclosed, a doubtful blessing. It distributes oil vapour and spray impartially, and the chain still requires periodical attention.

This is an important point as regards external cleanliness which makers would do well to bear in mind.

**Another Lady Rider on War Work.**

Most lady riders of the early days have proved themselves to be of the practical sort in this time of scarcity, and yet another well-known lady competition rider to give up her time to war work is Miss Mary Reid, who is now employed at the factory of Brough motor cycles.

**For Prisoners of War.**

In March, 1916, the R.A.C. started a fund to provide food and other necessities for the civilian motor drivers interned at Ruhleben. These men were in civilian service in Germany at the outbreak of war, and most of them are still enduring a most tedious existence as prisoners at Ruhleben, where they suffer many hardships and indignities.

Since the R.A.C. fund was opened parcels have been despatched weekly, and many letters and postcards have been received from the interned men stating how much they have appreciated these donations, which have helped to make life possible. Moreover, these parcels show the men that they are not forgotten by their more fortunate friends safe in England.

The R.A.C., however, has recently lost many subscribers to the fund, which is in need of further support, and we are asked to announce that support of this worthy cause is urgently needed—even the smallest amounts being useful. Address, R.A.C. Presents of War Fund, Royal Automobile Club, London, S.W.

**The Metric Measure.**

The General Assembly of the French Chambers of Commerce has expressed the hope that Great Britain, Japan, and Russia will adopt the metric system.

**Aluminium and Air-cooled Engines.**

The use of aluminium for cooling purposes is not nearly so new as the average man supposes. *The Motor Cycle* has investigated its origin, and attention is drawn to an informative article in this issue.

**A Fast Touring Mount.**

A member of our staff recently undertook a 300 mile trip on an overhead valve flat twin—the latest production of the Brough factory. For fast touring and maintained high speeds this type of engine is almost a revelation, rivalled only by a good T.T. Scott.

**The Humble Hack.**

In these days most of us find it necessary to augment the motor cycle by the occasional use of a pedal cycle, and a very useful auxiliary it proves. Yet we who pride ourselves upon our mechanical aptitude find we are very prone to subject our humble pedal cycles to a neglect we should deem criminal in the case of the mechanically-propelled machine, till one day an irritating squeak awakes us to the fact that "the poor old beast wants oiling." We owe much to the pedal cycle, yet it is so easy to forget.

WHAT THE LATEST TANKS CAN DO!

Incidentally the reproduction shows what the men of the Tanks can do too, for the excellent drawing is by a gunner of the Tanks. It represents Tanks on their way to the line, Gnr. E. Fuller's inspiration for the drawing being obtained from another Tank in company.

# THE "ISLE

A series of exclusive photographs showing aspects of the Front the French Army have held the line opposite to the places southward, comparatively few of our men have been in these

I AM now at the Front again with my Heavy Artillery Group, though not yet quite recovered. To my regret, I shall not be able to ride a motor cycle again for some time, but I long intensely to be astride my Triumph once more. As an Ally and Frenchman, may I express the hope that after the war the English D.R. and other motor cyclists will visit France, either to see the parts of our country which have been the theatres of battles, or to spend a holiday touring midst the beautiful scenery and on the good roads that France possesses? Landscapes we have of sufficient charm and variety to please the most fastidious traveller in all

his requirements.

These photographs show a few of the aspects of the "war zone," parts of the French Front which are but little known to the English soldiers.

I have had the opportunity of covering all the Front in France from the sea to the *frontière* whilst with the Heavy Artillery. The departments of the Pas de Calais and of the Somme are too well known to our English friends for me to speak of them: but I feel obliged to say that we are thankful for the gallant efforts they make every day to push back the Huns' occupation.

We took for a time the Aisne sector between Compiègne and Soissons. This part is called the "Isle of France," and it is a very beautiful part of the country, the valley in which the River Aisne calmly runs being particularly interesting.

No. 1. The castle of Vez, near Villers Coterets. This picture shows the perfect state of the roads.

No. 2. A road on which traffic is suspended in the daytime. Soldiers guard the "limit," and in order to hide there are screens made of branches suspended from wires, or fences of straw, along the way.

In No. 3 one can see the heights occupied at that time by the Boches. Note the splendid road which curls down the hill on the right. This was taken in the wine-producing district. The very celebrated wines of this lovely country are

# OF FRANCE."

yet little known to our fighting men. Up to the present recorded, and though we are gradually extending our line of observation.

(By a Correspondent in the French Army.)

The map will assist in locating the scenes described.

appreciated all over the world, but Rheims and Epernay, where they are made, are not sufficiently known. They are gay and delicious little towns! The lives of the inhabitants there seemed happy and the people very kind. The ground is undulating, and the wine fields give a tint of green, blue, or yellow, according to the time of the year, the red and white buildings of the villages nestling together making very picturesque scenes.

No 4. Vine fields near the German lines. The plain for five miles distant is under observation by the Huns, and the D.R.'s sometimes suffer on account of this.

From the picture No.

one obtains an idea of the splendid and fast roads erected to speed men. This is the highway from Reims to Rheims, and on its fine surface the fastest machine seems slow. The trusty Triumph is seen on the roadside.

No. 6. A canal lateral to the Meuse; the road alongside leads to the famous city of Verdun. In the barges beneath the trees soldiers are billeted.

No. 7. The River Meuse and the little village of Verdun in the background.

No. 8. A D.R. studying the locality by means of a map. One would hardly believe that delightful the scene is quite near the firing line.

When one goes further east the country becomes more over, and woods commence to cover the ground, and it has a savage type of beauty all its own. You are in the Argonne country, and midst the terrible Verdun sector, which is among the worst for desert riding in the whole of France. The battle had been raging when I visited this part, and the traffic was intense and the mud simply awful.

I hope to get even by calmly touring, when peace arrives, on a good English motor cycle in these places, where the war will have left such unalterable and powerful impressions. I hope also to meet on the way many of our gallant Allies and friends—if you will allow me this term—who may be visiting these scenes of ineffaceable memories. H. E. PLATEAU.

## CANTILEVER SPRINGING.

How the System is appealing to Manufacturers. Three Designs now under Test.

THE methods adopted in the springing of motor cycles are many and various.

Leaf springs perhaps predominate, and rightly so; but coil springs, too, are used very effectively on many machines. The special advantage of the leaf spring is, of course, the damping effect of the friction between the leaves. This eases and absorbs the rebound, which would otherwise take place after the obstacle was passed. The leaf springs favoured generally take the form of quarter-elliptic. This has the advantage of keeping the weight down to a minimum where leaf springs are employed, but the springs must be very securely anchored to a part of the frame which is sufficiently strong to carry the weight. The grasshopper, or cantilever, type of spring is in itself heavier than the quarter-elliptic owing to its greater length and the necessity for increased stiffness if the springing movement is not to be somewhat excessive, but the anchorage may be lighter.

### An Early Adaptation of the Cantilever Spring.

It is not generally known that one of the first firms to experiment with a cantilever system of springing was the Hendee Co., and on March 7th, 1914, Mr. Oscar Hedstrom's patent, covering a cantilever design of spring frame for Indian motor cycles, was filed. The sketch we give on this page shows the principle of this patent, which, it will be seen, is very different from the Indian system of rear springing with which we are all familiar.

The Indian Co. has very thoroughly

tested the design here shown; but Mr. Hedstrom does not consider this type of spring frame so good as the original Indian design, which is still in use.

A patented design of cantilever springing as fitted to an Indian frame.

On November 2nd, 1914, Messrs. Douglas Bros. applied for a patent to cover their system of cantilever springing, which, in its improved form, is well known to our readers. In this design rather shorter springs are used than in the case of the Indian, while the Douglas frame certainly seems to be an improvement on the American design as regards reduction of weight.

On November 25th, 1915, a patent was granted for yet another system of rear springing which involved the cantilever principle, the James spring frame being, perhaps, most remarkable for the unusual length of the springs used, these

extending from a point above the centre of the rear wheel to the brazed junction which generally supports the front side-car coupling. The springs are pivoted centrally, and, owing to their great length, a very wide range of vertical movement is permitted to the rear wheel, though the weight seems rather high.

### A Promising Design.

Each of these three interesting systems of springing is the work of a highly practical designer, and it will be interesting to note whether the cantilever

Details of the Douglas cantilever spring frame. Its construction insulates the carrier from shocks sustained by the wheel spindle.

The James cantilever spring is pivoted centrally, a good deal of vertical movement being possible owing to the unusual length of the spring.

system, which offers certain unquestionable advantages on paper, will hold its own against the more common quarter-elliptic type. Though similar in principle, the three designs differ to a more or less appreciable extent in matters of detail and in the method of application. On paper the cantilever springing of motor cycles looks extremely promising; it is neat in appearance, and, by reason of the suppleness afforded by such a long leaf spring, suggests the maximum comfort on rough surfaces. Yet it is curious that, although three different firms have devoted attention to the design, as proved by the fact of patents having been obtained, none have been standardised for public sale. Probably had the times been more favourable, Douglas Bros., at any rate, would have listed their spring frame model, since it has already passed through different stages of development.

## MILITARY NOTES.

## AUSTRALIAN D.R.'s.

**A**RT.-CPL. C. H. FISHER, speaking of the despatch riders attached to the 3rd Australian Division in France, says:

"In the big push of the last few weeks the men and machines have done a lot of hard work. I am glad to say that all the boys are still above ground; and as to the machines, the old Triumphs, they also have stood up to it well.

"We are now out for a rest, which is certainly due and will be appreciated."

□ □ □

## WAR-WORN MOTOR CYCLES FOR WAR-WORN MEN.

**P**TE. J. F. SPENCER, A.S.C. (M.T.), writes from France as follows: "I am very interested in the article describing the dump of disabled motor cycles. Do you not think that those who have taken an active part in the field should have the first opportunity of purchasing a mount from this source?" We quite agree if the motor cycles are to be offered for sale. He goes on: "The article by A. J. Sproston on 'After-war Problems' is quite in accordance with my ideas. Undoubtedly the four-cylinder engine for sidecar work will come into its own."

Spencer was a well-known member of the Coventry and Warwickshire Motor Club, and formerly joint proprietor of the Priory Accessories Company.

□ □ □

## AN AMERICAN RIOT CAR.

**A**MONG the motor war vehicles which are being made by our Allies in the States is the Cygnet Riot Car. In the event of a riot or disturbance, the outfit can convey four men to the

MOTOR CYCLIST D.R.'s OF THE 3RD AUSTRALIAN DIVISION  
(Top) Cpls. Fisher, Dolg, Egerton, Werrin, Benner, and Blanch.  
(Kneeling) Cpls. Hollins, Shaw, Spr. Wylie, Cpls. Symes, Hitchbrooke, and Traill  
(Bottom) Cpl. Lightwood and Spr. Cotton.

scene of trouble very quickly. The construction of the body is such as to provide for holding standard rifles underneath the seats.

In addition to being of value in regular military work, this model is also becoming very popular in the equipment of home defence organisations. The illustration given is of one of several outfits supplied to the Lewis Machine Gun Company (Montclair, N.J., Battery).

## A TRIO OF MOTOR CYCLISTS IN THE R.F.C.

**R.** O. CLARK, of Norwich, who was a leading exponent of the F.N. machine and well-known to competition men, is an Equipment Officer of the R.F.C. (Motor Transport Section). Two other motor cyclists well known to a large section of our readers are E. Kickham, the Bristol motor cycle agent, who is a 2nd air mechanic, and F. J. Watson, of the Motor Cycling Club (London), who has scored many notable successes on Ariel machines.

□ □ □

## HE AND SHE TANKS!

**D**R. ADDISON, Minister of Munitions, reviewing in the House of Commons the position of war munition supplies, remarked, concerning the Tanks: "The Tank made his appearance last autumn. I say 'his,' for we distinguish a male and a female variety. At the close of last year much work required to be done in the way of alteration and improvement, as the experience of the Somme suggested, but the supplies of the new designs are coming forward excellently, and the end of the story is not yet, for the enthusiasm of Col. Stern, Sir Eustace d'Eyncourt, and their colleagues knows no limits."

□ □ □

## LOSS OF THE EASTERN MAILS.

**T**HE Postmaster-General announces that the letter mails for India, the Mesopotamian Expeditionary Force, Ceylon, the Straits Settlements, and beyond, and also for Australasia, which were despatched from London on May 31st last have been lost at sea, also the parcel mails for the same destinations despatched on May 23rd. The same fate has overtaken letters and newspapers for the Salonica Force posted on May 22nd, May 24th, and June 9th.

The Cygnet Riot car is employed by the Home Defence organisations of America, and used to convey men with rifles in case of trouble.

The Editor does not hold himself responsible for the opinions of his correspondents.  
All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

#### AN APPRECIATION OF THE P. AND M.

Sir,—With regard to the speed of the P. and M. motor cycle, to which several references have recently been made in your columns, I think the impression that the speed of these machines is not equal to other motor cycles of similar power has been formed from the fact that the great bulk of the P. and M. machines have been geared by the manufacturers for sidecar work. As a matter of fact, the design of the engine and transmission ensures as high a speed as it is possible to obtain, taking into consideration the necessary durability of the parts for ordinary work.

It is a fact that machines turned out from the works, standard in every respect and geared at  $5\frac{1}{2}$  to 1, have, on several occasions, lapped at Brooklands (two miles 1,350ft.) at 50 m.p.h., which represents an engine speed of nearly 3,400 r.p.m.

Any P. and M. machine, with the standard solo gear ratio of 4.8 to 1 is capable of a speed of 50 m.p.h., without any alterations to the standard timing, compression, etc.

B. MARIANS.

#### PETROL ALLOWANCES.

Sir,—Like you, I must say I feel considerably annoyed when I see in the press that meaningless "squealing" suggesting that the Petrol Control Committee has been over-generous in the granting of permits. Probably the squealers would change their tune if they knew what the restrictions really mean to those who are compelled to live in a remote mining village. It is all very well for those to talk who have a station within easy reach, tramway cars, "taxis" at stands, etc., but let them imagine themselves in my position, for instance. Our railway station is two miles off and very few trains run to it. The nearest town (Ayr) is  $10\frac{1}{2}$  miles off by road (return fare 3s. 6d.) To get to the station a hire costs 3s. Now we cannot possibly get everything we want in the village. But in addition to that it is not a case of pleasure-seeking when I say it is essential for me or anyone else to get out of here occasionally. Just try to imagine how nerve-racking it is to teach day after day in a mining village where there are no means whatever of obtaining any mental relaxation—no library even. I do not think it is a case of pleasure-seeking when I say an occasional change is essential to make life possible. With my bicycle and sidecar I can take my wife and two little children to Ayr for about one-third gallon of fuel. Now I must hire a machine to the station (3s.), two full return fares at 3s. 6d. (7s.), two half return fares at 1s. 9d. (3s. 6d.), total 13s. 6d., against, say, 1s. 6d. or so by motor cycle. "Some" war economy!

Of course the "squealers" say, "Stay at home always." My answer to them would be, "Come and live in a remote mining village for a time, and then you will know what you are talking about." Again, the doctor who attends the village lives five miles off by road and is not on the telephone; he might be another five miles off on the other side when you go for him. The nearest chemist and druggist's shop is five miles off. Along with this, as I pointed out to the Control Committee, I am absolutely forbidden to ride a pedal cycle. However, the Petrol Control Committee has quite made up its mind that if anyone connected with me becomes suddenly ill and requires a doctor or drug, that person must just die. All these facts have been put before the committee, yet it cannot even see its way to allow me a gallon a month to keep in case of emergency.

Ayrshire.

NO JOY-RIDER.

#### AN IDEAL MOUNT FOR A LADY.

Sir,—I see "Cadet" mentions "more miles per gallon"—my  $2\frac{1}{4}$  h.p. Velocette used exactly half a gallon of petrol in the forty-nine miles between Worthing and Kingston, and ran on the high gear the whole way. Its usual speed, when nearly throttled down, is 20 m.p.h. by the Stewart speedometer. On the way home it occurred to me that there is so little to do in managing this little machine that I am liable to forget that there is anything at all to be done—except just to guide it round corners and restrain it through villages. There is no kick-starter, but two or three pushes are enough to make it start. I expect you know all about Velocettes, but I have talked with other women and these are the things they wanted to know.

A.B.

Worthing.

#### SHOCK FROM A SOOTED PLUG.

Sir,—"Ixion's" comments are generally so excellent that I received a shock far worse than any obtainable from a sooted or unsooted plug on seeing his remarks on "Shock from a Sooted Plug" in *The Motor Cycle* of June 28th. He says, "Popular electrical manuals assert that electricity always selects the 'shortest' road home"; and after suggesting that this means the path of least electrical resistance, says, "Perhaps, therefore, a sooted plug will only give a shock at its outer terminal when the short-circuiting path offers less electrical resistance than the alternative path down the central wire of the plug and across the carbon bridge."

Am I really to understand, sir, that "Ixion," the joy of my motor cycling youth, the prop of my declining years, does not know the simple rule that the flow of current through alternative paths is inversely proportional to the resistance of those paths? That is to say, that if there are two paths for a current, one offering (say) ten times as much resistance as the other, the current will not confine itself to the path of least resistance, but will flow through both, though the current flowing through the path of least resistance will be ten times as great as that flowing through the other path.

When this simple principle is grasped, "Ixion's" problem ceases to be a problem.

Norwood, S.E.

SHOCKED.

#### THE ADVANTAGE OF THORN CATCHERS.

Sir,—I am an engineer by profession, and have always done all my own repairs, keeping my machine in good condition. My home is about thirty-six miles from the works at which I am employed, and I use the motor cycle in order to spend almost every week-end at home.

My machine is a 4 h.p. Bradbury, which I have had since 1911, and it has given me splendid service. I have, of course, modernised it, fitted adjustable tappets, etc., and in 1914 I fitted to it a N.S.U. two-speed gear.

I always carry "thorn catchers," and cannot understand anyone riding a motor cycle without something suspended around the tyre to knock off the thorns, nails, flints, etc., which simply cannot penetrate the tyre at the first impact. The result is that roadside repairs are very rare indeed with me. As a matter of fact, after nearly four years of frequent rides between Briton Ferry and Pontypridd I have only, to my recollection, had two punctures, though I may have had a few while on other rides. Both these punctures were obtained at the time my "catcher" was missing.

Though many readers may scoff, I can state that, taking only my mileage since the petrol licences came into operation and allowing for bare gallons marked thereon, nothing allowed for shortages in tins, which are frequent, flooding,

cleaning oil spots off clothes, etc., in nine months' riding, I have just run over 100 m.p.g. on a 30 B. and B. jet.

My troubles have been very few indeed, confined practically to (1) violent contact with an Airedale dog at about 30 m.p.h., which was bad for the bicycle and very much worse for the dog—I got off with a shaking; (2) during the cold weather this year I had trouble on four or five mornings in starting up, but after taking off the inlet valve cap and warming it on a gas stove I could always start up at once.

In my opinion, singles cannot be beaten for reliability and economical riding, and no doubt there are hundreds of practical mechanics who prefer an old "big single" with an engine-shaft speed gear or Philipson pulley. These fairly ancient machines have very little about them to go wrong, and they are also very much lighter than modern counter-shaft machines—a decided advantage.

Pontypridd.

CYMRO.

### BALL BEARING CONNECTING RODS.

Sir.—May I be allowed to reply to "Pip-Emma" by saying that the main points of his letter in your last issue do nothing but corroborate my contention that the rotary engine is a reciprocating engine, and I quite agree with all that he says, except the last two sentences?

The crank pin centre is a point fixed outside the circle of the crankshaft, and is therefore concentric.

I did not lose sight of the fact that the pistons describe a circle during a revolution of the engine, and that the centre of that circle is the crank pin; nor of the fact that this piston circle, being within the circle described by the cylinders, is eccentric thereto; nor of the fact that the eccentricity of these two circles represents the distance that the pistons reciprocate along the cylinders.

The pistons have two motions—one rotary relative to the crank pin; the other is a reciprocating motion relative to the centre of the crankshaft and to the cylinders. The pistons come to rest at each end of the stroke, and accelerate and decelerate quite the same as a piston in a stationary engine; but, while they are at rest at each end of their reciprocating stroke, they are certainly not at rest centrifugally. In this sense only can the pistons be said to be never at rest.

Your correspondent must agree with me in that the pistons move to and from each end of the cylinders; if he does, then he must agree that the piston is a reciprocating part. The rotary motion must not be confounded with the reciprocating motion; they are two separate and distinct motions. The former motion is a resultant of the latter. If an engine possesses a crank which moves a piston, or a piston which turns a crank, then that engine must unquestionably be an engine, or machine, with reciprocating parts.

The reciprocating "effect" which your correspondent mentions at the conclusion of his letter is a fact; the expression "effect" seems to convey something of an illusory character.

The only true rotary engine is the turbine.

PICARDY PITT.

Sir,—I cannot pass "Picardy Pitt's" remarks in your issue dated June 21st, lest your readers might think I agree with them. As a matter of fact, there is practically nothing in his letter which throws any additional light on the subject under discussion, but there is much in it which might confuse your readers should they take it seriously.

First, let me advise "Picardy Pitt" to read "J.C.B.'s" letter in your issue for May 24th. Perhaps he will then understand my reply to that letter in your issue for May 31st. My letter does not contain any "very obvious errors," as "Picardy Pitt" would like to make out. I do not withdraw one word of that letter, and claim that my statements are quite clear, correct, and intelligible to anyone with a moderate knowledge of mechanics as applied to the petrol engine. Unfortunately—as I know too well—there are a number of persons masquerading as aero engine mechanics, who have little or no knowledge of the underlying principles of the aero engine. Briefly I will answer some of "Picardy Pitt's" statements.

Paragraph 2. The rotary engine certainly is not a reciprocating one, but the rotating cylinder engine has a few slightly reciprocating parts, such as valves, rockers, tappets, etc. I made no inference that radial and rotary engines are of the same class, excepting that the connecting rods are all brought together at one point on the crankshaft.

The Gnome, Clerget, Gnome monosoupape, and le Rhône are not true rotary engines, but rotating cylinder engines. An engine containing reciprocating parts cannot be a true rotary engine, although the term "rotary" is commonly applied to the above engines.

Paragraph 3. If "Picardy Pitt" had realised the difference between my "given point" (crank pin) and the "central point" (crankshaft) in his statement, all the wind in this paragraph would have been saved. I made no such statement that "the pistons, through their respective connecting rods, are being whirled round a central point." My statement says "round a given point" (crank pin). I repeat this now, and add that in the Gnome, Clerget, and Gnome monosoupape the pistons follow practically a circular path, and in the le Rhône a true circular path, in space. The pistons do not reciprocate in space, as they do in a stationary engine.

Paragraph 4 is all very interesting, but the majority of it has no bearing on the subject under discussion. The only important part of it bearing on ball bearing connecting rods is that near the end of the paragraph, where eleven lines are wasted to tell your readers what I had already told them in six lines in my letter of May 31st.

TECH. SGT.-MAJ., R.F.C.

Sir,—Re the letters under the above heading from "Picardy Pitt" and "Pip-Emma," the following diagram may serve to elucidate this matter further.

The crankshaft A is, of course, fixed, as is the crank pin B. The cylinder rotates about point A, and the piston and connecting rod about point B.

Now it is easily seen that the motion of the piston in space (provided the engine is stationary in space) is a circle. It is equally evident that the motion of the piston relative to the cylinder is reciprocating.

A diagram to show the movement of the piston in the cylinders of a rotating engine.

As regards stresses on the big end bearing, these will be the same as in the stationary cylinder type, but modified by the action of centrifugal force on the piston and connecting rod. During the compression and firing strokes the stress on the bearing will be less than in the stationary engine by an ascertainable amount, and during the other periods will be greater by a similar amount.

As to whether the engine is of the reciprocating type or not depends on the accepted definition of a reciprocating engine.

If the term "rotary" engines excluded all engines except those in which the whole moving part or parts revolve round a fixed axis with the same angular velocity, then the term rotary would cover only steam, gas, or water turbines.

Again, if the term "reciprocating engines" included all engines in which any part or parts have with respect to any other part or parts a reciprocating motion, then the so-called rotary engine under discussion would come under this heading.

It would seem, however, to be generally understood that a rotary engine refers to one in which the cylinders move in a circular path round a fixed axis.

ENGRO.

Baildon, Yorks.

## ALUMINIUM CYLINDERS.

Sir,—We have been interested in reading Mr. G. Funck's article in your issue of June 21st in regard to aluminium alloy pistons, and we would desire to direct attention to one point which he raises.

Amongst the "some disadvantages" which he states aluminium alloys possess, the first is given as "small tensile strength." This is, of course, quite correct in so far as pure aluminium is concerned, and is also correct in regard to many of its alloys. But there are aluminium alloys which will compare favourably in this respect with cast iron. Thus, Magnalite has a tensile strength of 27,000 lb. per square inch, and Aerolight 28,000 lb. per square inch, which is, we believe, substantially higher than that of cast iron. Cast iron varies considerably, but the average tensile of this material is in the neighbourhood of 16,000-17,000 lb. So that it would appear that either of these materials would be perfectly suitable for aluminium cylinders without any need for steel or cast iron liners.

The only point in regard to liners which we have no definite information upon is as to the frictional properties of the alloys. In other words, how alloy cylinders unlined would stand the working of the piston.

BRANCO, LTD.

## TWO-STROKE V. FOUR-STROKE.

Sir,—I did not wish to enter into correspondence, but I cannot refrain any longer. I am not an old motor cyclist, but have driven my own motor car and done the running repairs for six years; and in order to be a companion for my boy, I purchased a 2½ h.p. Sun two-stroke in October last. I had previously bought him a 2½ h.p. Levis two-stroke, and these two machines are giving every satisfaction.

About six weeks ago we started off together from Birkenhead to Bala, Barmouth, Criccieth, then home by Beddgelert, Bettws-y-Coed, Abergelle, and Queen's Ferry, and our mileage worked out at 110 miles per gallon. I am 12 stone weight, and was able to go ahead up hill and down without any trouble whatever.

How anyone could wish for a better performance than this is a mystery to me; and the idea of purchasing a four-stroke, with valves to grind in, tappets to adjust, and not nearly such an even pull as a two-stroke, is also a mystery to me.

I am a practical engineer with thirty-five years' experience of all classes of engines, and think there is no doubt whatever that a simple engine like the two-stroke is undoubtedly the engine of the future, as it is cheaper and better. Usual disclaimer.

TEMBAL.

Liverpool.

Sir,—I was considerably interested in "The Critics'" discussion concerning the two-stroke and four-stroke in your issue of May 31st. As I have been a constant reader of your valuable paper for some years, and have never before put forward my humble opinions in your columns, I hope I may be allowed to say that I do not agree with the popular opinion that the two-stroke is more extravagant than the four in fuel, but poor consumption on any particular machine is without doubt due to faulty carburetter adjustment, or in many cases to an unsuitable carburetter. A great many carburetters fitted to two-stroke machines have an inlet pipe of the same diameter as would be fitted to a 500 c.c. four-stroke single. This when fitted to an engine of something like 225 c.c. is not productive of the most economical results, the jet, of course, being correspondingly large.

In previous issues of *The Motor Cycle* the extraordinary economy of the Velocette has been described and commented on, but I myself have obtained the same economical running from a Connaught. I could always reach well over 100 m.p.g., and the oil consumption was not at all large, but, unfortunately, I cannot now give the exact figure. The petrol system is used on the Connaught, and the makers advise six measures full of oil to one gallon. I have, however, found four to be quite sufficient. A friend owned a two-stroke of another make fitted with a well-known carburetter, which would have done full justice to a 5-6 h.p. single-cylinder of 700 c.c. Naturally, his fuel consumption was more than double mine, less than 50 m.p.g. being about his average.

But, although the two-stroke is economical, I think its working principle far inferior to that of the four-stroke

machine. The intermingling of the fresh gas and the exhaust gas cannot be prevented by any type of deflector, and thereby the mixture is upset, and consequently we do not get the beautifully sharp and powerful explosion of the four-stroke, i.e., a well-tuned four-stroke. I do not consider that the acme of perfection is an even torque. What I like is to feel the powerful "punch" of a T.T. single behind me, and not the even torque of a two-stroke or flat twin, which is no more exhilarating, to my mind, than travelling on an electric tram, where undoubtedly you get an ideal even torque.

L. AGAR.

## WHY DOES AN ENGINE KONK?

Sir,—As an interested reader of the correspondence columns of your excellent paper I have followed the discussions on the subject of konking for the last few years, but have not seen anyone advance the theory which I hold on this subject, namely, that this is caused by pre-ignition—not by the points of sparking plugs being incandescent or by sharp points on projecting objects in the cylinder, but by the same medium that is taken advantage of to fire the charge in the Diesel engine—i.e., the heat of the compressed contents of the cylinders. People familiar with the construction of the Diesel engine are aware that the charge is not fired by magneto or similar device, but the air is compressed to such a pressure (and resultant temperature) that when the fuel is admitted the heat of compression is sufficient to ignite it.

The motor cycle engine has normally a low compression (comparatively speaking), and, consequently, the pressure and temperature are not high enough under ordinary running conditions to ignite the mixture, and ignition does not take place until the spark passes across the plug points. After hard running, however, or climbing a hill, the increased temperature of the cylinder, combined with the heat of compression of the charge in the cylinder, is sufficient to ignite the contents before reaching the end of the stroke, thereby producing a blow on the piston in the direction opposite to its travel. This theory is borne out by the fact that high compression engines are more prone to konking than those with low compression.

I should be glad to have your readers' ideas.

FRANK SMITH.

## SHOCK ABSORBERS.

Sir,—I have read with interest "Wharfedale's" criticism of my article dealing with transmission shock absorbers, but I certainly do not admit that in advocating the friction device contained in the rear wheel sprocket I perpetrated a fatal blunder. The torque delivered to the rear wheel, when ascending a steep gradient on bottom gear, is not so great as the momentary snatch delivered by a gear of four to one at a medium speed. In other words, if the rear wheel shock absorber were adjusted to absorb the snatch of a 4 to 1 gear, it would, with the engine delivering an even torque on its bottom gear, possess sufficient grip to propel the machine up—should we say—Park Rash, a hill with which "Wharfedale" is perhaps familiar. As an analogy, it is an easy thing to hammer a nail into a board, but the same nail would take a mighty lot of pushing in; similarly the rear wheel shock absorber would yield to a sudden blow, but it would require a tremendous constant turning effort to cause it to revolve independently of the wheel.

"Wharfedale" should also bear in mind that very little slip at the rear wheel is effectively equivalent to five or six times the amount at the engine shaft, the proportion increasing as the gear ratio is reduced. If his theory were correct the belt of a step drive would not function at all as a shock absorber when on top gear, unless so slack as to be incapable of propelling the machine at all on full load and its low gear ratios!

With regard to high gear low speed work, I think it is expecting too much of any shock absorber, the adjustment of which is a matter of compromise, to take up such inequalities in the drive—especially in the case of a single. The thump or thrust of such an engine at such a time is quite distinct from the chain snatch which a transmission shock absorber is intended to eliminate, and can only be absorbed by the use of a hand-controlled clutch—as "Wharfedale" suggests—by which the amount of slip can be governed to meet fluctuating requirements.

CHINOOK.

## KEEPING FIT.

In which the writer advocates the heavy sidecar outfit for general use.

THERE have been several comments in *The Motor Cycle* recently on the weight and power of sidecar outfits, and, although the general summing up seems to favour the medium power, I certainly regard a heavier and more powerful outfit as more to my fancy.

My home is in an old rustic, stationless village in the vale of Glamorgan, the nearest market town being Bridgend, about seven miles away. Naturally I find my New Hudson "Big 6" indispensable, especially on market days.

### Coal Mining and "Joy Riding."

I am a collier, and would like to say how amusing are the carpings of those venerable humbugs who write daily in the press about joy riding, waste of petrol, etc. One has to keep fit, and half an hour on the "old 'bus" does more in eliminating the evil effects of the vitiated mine atmosphere than all the drugs in creation.

I find the New Hudson "reliability itself"; it glories in hard work, and loves to slog up inclines, and it is a severe gradient which occasions a drop into second gear.

The handle-bar clutch control I find very useful in traffic. I have substituted the original carburetter for a Binks, and the economy effected thereby has well repaid me; were it only for the simplicity of this carburetter I would readily advocate it. With it the machine runs beautifully on substitute when once it is warm, but, of course, I keep my engine in good tune.

### Electric Lighting.

The head light was made from an old car lamp with the help of the village blacksmith. I use a 40 amp. accumulator, boxed firmly underneath the sidecar seat; the switch I found necessary to conceal from

the interested efforts of small boys. Both front and rear lamps are supplied from the same accumulator, but I have connected them in parallel, as I use slightly more current in the head lamp. It may be interesting to know that of all bulbs I have found none to equal the British Thomson-Houston Mazda filaments. I put one of their new half watt bulbs in the head lamp, and, although only 4 volt 1.5 amp., I can almost recognise a man at the distance of two telegraph poles,

while the lamps consume only half the current for this same candle-power. I would like to advise owners of electrically-equipped motor cycles to try them.

### A Week on the "Bummel."

My longest trip was to Bristol via Gloucester, about 130 miles. It was during this "bummel" that I had my first involuntary stop. My petrol pipe broke close to the carburetter. Oh! those pot-holes! The day was the Sabbath, the district a "no man's

land" just this side of Dursley, Gloucestershire. I had no rubber pipe, and insulation tape was useless. I had a cork—never mind its origin—and I cut it and pushed it tight into the bottom of the float chamber. I then took the top of the carburetter off, bent the petrol pipe up and over into it, and made a rough imitation of "top feed," filling the chamber from the tap near the tank. By guiding with one hand, and regulating the flow of petrol with the other, I got to my destination. My fair passenger told me, of course, when the chamber was full enough and *vice versa*—thus no waste. My petrol consumption was just a tank full (two gallons) going, and a little less coming back. I am about 11 stone, passenger 9½ stone, and about 50 lb. of luggage. My time worked out at about 22.7 miles per hour—quite a moderate average but an enjoyable touring speed.

The writer of the accompanying article aboard his well-loaded New Hudson 6 h.p. sidecar. He gives interesting details of his electric head light, which was formerly a car acetylene lamp.

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

### Dirt in Carburetter.

**Q** I have a 2½ h.p. Calthorpe-Jap, new in December, 1916, and have not done one hundred miles yet. It is fitted with a sight drip feed Best and Lloyd lubricator. This machine when run about two miles misfires and stops. I dismount, change gear, and start up again. This occurs when running in either gear about every two miles. Please tell me what is the matter.—NOVICE.

The trouble is probably due to some obstruction in the flow of the petrol. Make sure that no air lock is occurring either in the tank or the petrol pipe. For the first three or four hundred miles, until the dirt is washed out of the tank, etc., the carburetter will require a periodical cleaning out. To save trouble it is a good plan to half fill the tank with petrol and drain it out *via* the petrol tap, thus removing all foreign matter.

### Crank Case Release.

**Q** My machine is a 2½ h.p. four-stroke. How can I effect a good crank case compression release? I recently fitted a new main shaft on the pulley side, without the hole which was in the old one, through which excess oil was blown on to my left boot. To counteract this, when fitting a new shaft I put a ⅜ in. hole in the shaft on the timing side, but I was obliged to stop it up owing to oil being blown into the timing case and magneto chain case, and thence on to the magneto, which proved fatal. There are still two small holes in the above bearing, from crank case to timing chest, and two holes from timing chest to magneto chain case, through which a considerable amount of clean fresh oil still blows. Should I fit some kind of release direct to the crank case?—E.G.W.

Of course, the oil would naturally do no harm in the timing case. Perhaps you might try opening it again and fitting a short copper pipe from the timing case, carrying it away clear of the engine, so that any excess of oil is blown on to the ground. This would ensure the timing wheels receiving an adequate supply of lubricant and yet keep the magneto clear. If, however, after doing this, you still get oil on the magneto then you would have to buy a relief valve and fit it on to some convenient part of the crank case. A release is not, of course, essential, but without it oil is likely to be forced out of the joints.

### Incorrect Mixture.

**Q** I have a 4 h.p. single, to which is fitted a Senspray carburetter. I have tried all sizes of jets, from the smallest to the largest, bound all joints with insulating tape to prevent any air leaks, but have been unable to prevent my engine from eight-stroking. I might add that I cannot give any air until the throttle is three parts open.—H.G.H.

As you have tried various jets your trouble is probably due to the petrol level in the carburetter being wrong. Has the clip on the needle, against which the float bears, by any chance been replaced wrong way up? The level can be raised by placing one or more small brass washers on the top of the clip, or lowered by placing some light packing, such as a mica washer, between the clip and the float.

### IMPORTANT NOTICE.

#### GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD

### Unsatisfactory Running.

**Q** (1.) I possess a 1913 3½ h.p. Rudge Multi. I run on an average 100 miles per week, without trouble, but when going along nicely the engine will suddenly become sluggish, and no amount of coaxing by changing gear or altering the controls will induce it to go, and it will eventually stop; but if I raise the exhaust for a second, and drop it suddenly, it will go forward with a plunge. What is the cause? (2.) I can get only 50 m.p.g. I use a 44 jet Senspray, and a smaller one is of no use. I always run on petrol. Could you suggest any improvement to obtain better consumption? (3.) Should it be capable of taking a light coachbuilt sidecar, with passenger, in S. Wales district, which, as you are aware, is very hilly?—W.C.

(1.) The symptoms you describe are rather curious. It seems to us that there may be a possibility of the carburetter flooding badly, and that you are running

on too strong a mixture. The fact of raising the exhaust allows an excess of petrol to be expunged from the cylinder, and stopping the suction on the jet allows the machine to recover itself. Again, the trouble may be due to the exhaust valve stem sticking slightly in its guide and preventing the valve closing properly, or to the same effect caused by the exhaust valve tappet sticking in its guide owing to insufficient oil reaching it. (2.) Overhaul the petrol system carefully, see that there are no leaks, and also do not fill your tank too full. Look over the timing, and see that the carburetter is not flooding. (3.) The machine should take a sidecar not exceeding 100 lb. all on.

### Too Large a Jet.

**Q** I have a 3½ h.p. 1912 T.T. Triumph. No matter how I regulate the control levers I cannot open the throttle any more than a third without choking my engine. I have overhauled the timing, magneto, and carburetter, and so far as I can see everything is all right.—R.G.T.

We think that if you fit a smaller jet you will be able to open the throttle to its fullest extent. You might try new valve springs.

### Valve Timing.

**Q** I should be obliged if you could inform me what difference there should be in the timing of a twin V engine to give the best results. (1.) I understand that one of the cylinders should be a little later in opening and closing of the valves. Which cylinder is this? (2.) I have a 1913 8 h.p. J.A.P. The timing of the cylinders is: Front—inlet opens dead top; inlet closes 20° past bottom centre = ⅜ in. up; exhaust opens 52° before bottom centre = ⅝ in.; exhaust closes 15° over top centre. Back—inlet opens 5° before top centre; inlet closes 10° over bottom centre = ⅜ in. (bare) up the stroke; exhaust opens 54° before bottom centre = ⅝ in. full (nearly ⅞ in.); exhaust closes 5° over top centre. The back cylinder has 5° to 10° advance over the front one. Is this correct, or should it be the same as the other, or should the front cylinder have the earlier opening and closing?—R.W.B.

(1.) The front cylinder may be slightly further advanced than the back. (2.) The timing of both your cylinders is too far advanced. If you time your back cylinder as your front one is now timed, it will give you just about the correct proportion on both of them.

**Converting an Old Machine.**

**?** I should be glad if you would kindly give me some information on the following points: I have a Minerva four-stroke, fixed engine 4 to 4½ h.p., direct belt drive, to which I wish to attach a sidecar. (1.) I should be glad to know if the belt drive would be sufficient, or should I convert the machine into chain drive? (2.) I also want the machine to start from standstill without having to run a distance to make it fire. I do not want a costly article.—M.C.N.

(1.) A direct belt drive is not very satisfactory for sidecar work. You would probably experience a good deal of transmission trouble. (2.) We cannot recommend you to spend money in attempting to convert an old machine—designed and made for solo use—for the attachment of a sidecar. The ultimate results might not prove satisfactory, and the machine would be worth little or no more when you came to sell it. A governor pulley or an engine shaft gear might prove a useful compromise, and by the latter you would be able to start the machine by jacking it up on the stand and pedalling, the gear in high, then putting the control in neutral and starting off on low gear in the ordinary way. If you wish to use a sidecar your wisest plan would probably be to sell your present mount and buy one better adapted to the work.

**Licences on Borrowed Machines.**

**?** A short time ago a friend of mine came over on his motor cycle to see me, and left the machine at my place. I had three runs of one mile, two miles, and forty miles. I have not had a motor cycle of my own for three years—but hold a driver's licence. The local police sergeant saw me on this machine, and he informs me that he is summoning me for riding without a Revenue licence. I should add that the machine was left with me twelve days; my friend is in the army—Staff-Sergt.—and is drafted about the country, and I cannot find him to ask if he has a Revenue licence. If not, am I responsible for him not taking one? Honestly, I do not know.—E.W.

Our legal adviser replies as follows: "The licence duty has to be paid by the one who keeps the motor cycle, and not necessarily by the party who uses it. I cannot see that there has been any case decided on facts anything like those given by your correspondent. I can hardly imagine that any Court would hold that he is keeping a motor cycle because a friend lent him one for twelve days, and I think it must be held that it was the owner who kept the motor cycle and simply allowed his friend to use it. If this be so, the fact that the owner had not taken out the annual licence does not affect your correspondent. If your correspondent had paid something for the use of the motor cycle, it would have been quite clear that the licence had to be taken out by the owner. This is provided for by Act of Parliament, in case of hirers of motor vehicles from garages."

**Metal for Engine Bearings.**

**?** I am thinking of rebushing my J.A.P. engine; and as phosphor bronze is difficult to obtain, I must resort to other metals. (1.) Would ordinary brass be suitable, or would mild steel or cast-iron be better? (2.) Can flywheels be satisfactorily set again (after having been taken down to renew big end) by scribing a line on the flywheels on opposite side to big end pin and setting with a straight-edge, or is it necessary to reassemble in lathe centres?—O.P.B.S.

(1.) Brass or white metal would be best for the purpose. We would not recommend you to use steel, as it would seize instantly if short of oil. (2.) A special jig is really necessary for resetting the flywheels, and we do not think you could manage it by the use of scribes and a straight-edge. You might obtain the correct centres by the careful use of a lathe.

**Testing a Second-hand Machine for Wear.**

**?** I am thinking of buying a second-hand 3½ h.p. o.h.v. three-speed clutch model Brough, but being a novice I should be obliged if you would tell me how and where to look for wear and any other faults. You will probably tell me to try the bearings, but what I want to know is how to.—J.C.O.

Try the bearings in the following way: Take the flywheel by grasping it with one hand on the top and the other at the bottom, then try lifting it, when, if the chain is reasonably slack, you will notice if there is any shake in the main bearing. Then by rotating the flywheel backwards and forwards; when the cylinders come up against compression, you will be able to tell if there is any shake in the connecting rod bearings. To make absolutely certain you would, of course, have to dismount one of the cylinders. Test the valve rockers by taking the rocker between the finger and thumb, when the pressure is off the valve, and see if there is any shake in the overhead mechanism throughout, and do the same with the tappets. Jack both wheels off the ground and note if there is any shake in the wheel bearings or the steering head. Note also that the wheels are tracking truly.

**An Oval Cylinder.**

**?** (1.) What is a rat-trap carburetter? (2.) I have heard that in aero engines the cylinders become oval through irregular cooling, and that brass rings are used to prevent this. If that is so, could I use these brass rings in my motor cycle engine, the cylinder of which has worn oval? (3.) May I use ordinary paraffin without a petrol licence?—W.J.M.

(1.) The term "mouse-trap" is sometimes used in connection with the type of carburetter in which the air intake operates in much the same manner as the door of a mouse-trap, as in the Binks racing carburetter. (2.) A special design of brass piston ring is used in certain aero engines—not to prevent warping, but to stop the escape of gases past the piston in case warping occurs. It is so arranged that the pressure of the gas above it tends

to open the ring; but we do not think this arrangement could profitably be applied to your engine. If the cylinder is worn oval, reboring is the only proper remedy. (3.) It is illegal to use paraffin unless it be entered on one's permit in the same way as petrol.

**READERS' REPLIES.****Lubricating Enclosed Fork Springs.**

In *The Motor Cycle* of June 21st, on page 580, I see a Rudge rider has been asking how to lubricate the front fork spring. The following is a simple method I adopted on an old machine and no further attention to this point has been necessary for over three years. The machine was first propped up by means of a box underneath the silencer in such a manner that the front wheel was clear of the ground and the fork spring and telescopic tube extended as much as possible. A small hole (about ¼ in.) was then drilled in the bottom spring tube as high as possible and in such a position that it was covered by the top spring tube when the machine was resting normally on the ground. Hot vaseline was then forced into this hole by means of the grease gun. Speaking from experience, I would strongly recommend your correspondent not to attempt to dismantle the front fork spring on his machine. The spring on my machine required renewing, and whereas the rest of the Rudge machine is delightfully accessible the front fork spring appeared to me at the time to be exactly the opposite.—D. E. NEWITT.

**Bending Handle-bars.**

Seeing "G.R.'s" question in *The Motor Cycle* of June 21st as regards bending his 1912 Triumph handle-bars from touring to semi-T.T., I thought I would write to let you know it can be done without an expert. My mount is a 1912 Triumph, and I recently bent mine over a gas ring, and was pleased with the result, and I may say that the heat did not interfere with the plating. The bars were heated and pulled outwards first, then put in the machine and heated again, placing a wooden wedge underneath and giving them two or three taps with a mallet. If "G.R." is within a reasonable distance of Peterborough I shall be pleased to show them to him.—EUSTACE WM. BROWN.

**EXPERIENCES WANTED.**

LLANGOLLEN TO NORTHAMPTON.—J.O.J.  
Llangollen, Chirk, Shrewsbury, Much Wenlock, Bridgnorth, Kidderminster, Bromsgrove, Headless Cross, Alcester, Stratford-on-Avon, Warwick, Leamington, Southam, Daventry, Weedon, Northampton. Approximately 130 miles.

LONDON (EAST DULWICH) TO FARINGDON.—H.G.W.

Dulwich, Herne Hill, Acre Lane, Clapham Park Road, Battersea Rise, Upper Richmond Road, Richmond, Hounslow, Cranford, Slough, Maidenhead, Henley, Wallingford, Wantage, Farringdon.

### Sidecar Springing.

In most cases the springs supporting the body of a sidecar are arranged on either side of the body in such a way as to give lateral support, and this, of course, increases the width of the sidecar with a body of given dimensions. The construction here shown comprises a built-up leaf spring, the lower member of which is attached to the main tube of the sidecar chassis, whilst the other is attached direct to the under-surface of the body. The body, therefore, can be

of the same width as the total space between the outer edges of the springs, enabling either a narrower construction to be produced, or a wider body to be fitted for a given width of sidecar chassis. It is stated that the particular construction of spring shown provides sufficient lateral stability, so that a neat and simple construction is arrived at.—C. T. B. Sangster, No. 104,749.

### Shock-absorbing Clutch Mechanism.

The invention illustrated comprises a plate clutch, with which is combined a resilient transmission device, a single spring serving both for the clutch and the spring drive. The chain sprocket A is connected to the sleeve B by a plate clutch C. On the countershaft D is fixed a screw-threaded sleeve E upon which

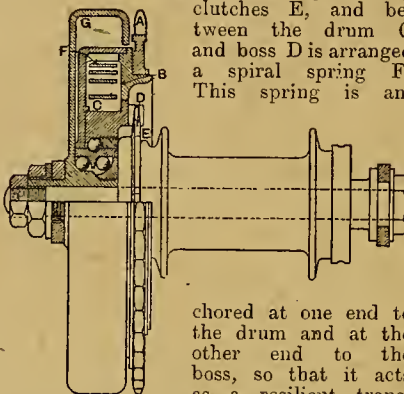

works a nut F, the outer edge of which engages splines G on the sleeve B. Between the nut F and a plate H is arranged a helical spring J. This spring acts through the plate H to press the sprocket A to the left, causing the clutch plates to abut against the stop K, and so engaging the clutch. At the same time, power transmitted from the countershaft D to the sleeve B or vice versa must necessarily

pass through the worm and nut device EF, and consequently violent shocks, instead of being transmitted from one member to the other, are absorbed by the spring J. This increases the spring pressure on the clutch plates, so that slipping is prevented. The clutch is disengaged by the cam ring L when required.—G. E. Stanley, No. 106,171.

### Spring Drive Mechanism.

The device is applied to a hub, the sprocket A being carried by a ring B, which is connected to a drum C at its outer edge, and free upon a boss D on its inner edge. This boss transmits the motion to the hub shell by the dog clutches E, and between the drum C and boss D is arranged a spiral spring F. This spring is an-

chored at one end to the drum and at the other end to the boss, so that it acts as a resilient transmission between the sprocket and the hub shell. The outer surface of the drum serves for the band brake, and this brake is enclosed by a stationary casing G secured against rotation in the fork end.—D. Levy, No. 105,358.

### Cooling Device and Trouser Guard.

There have been a considerable number of inventions relating to cooling devices for application to motor cycle engines, and the illustration shows a simple arrangement, the large view being a plan showing the cylinder in dotted lines. The

device comprises a cowl A, the sides of which are formed with louvres D facing the direction of travel, so that the air is caught and deflected on to the cylinder. The section shows the method of attachment of the cowl beneath the engine valve cap C. The plates of the cowl are indicated at D, and it will be seen that these act as radiating fins, and keep the temperature down in the neighbourhood of the valve caps.—F. M. Fletcher, No. 105,003.

### AVERAGE PRICES.

WE give below the prices of second-hand machines offered for sale in the last issue of *The Motor Cycle*, and in the adjoining column the average prices based upon the latest figures available. Thus the general trend of the market is visible at a glance, though in the first column many blanks inevitably occur. This is due to an insufficient number of one model on which to base an average. The word "combination" indicates a sidecar outfit as supplied complete by the makers.

Make.	Year.	H.P.	Average last week.	Previous weekly average.

### The Cameta Rubber Co.

The Cameta Rubber Co. have acquired the business of the Para Rubber Co., and are continuing business at the address, 93, John Bright Street, Birmingham, where a new stock of garments in all the latest styles is carried.

### A Vulcanising Handbook.

Motorists who own vulcanising plants should write for the new edition of the Dunlop vulcanising handbook. Address Advertising Department, Dunlop Rubber Co., Ltd., Aston Cross, Birmingham.

**There's nothing like it**

—nothing in belts that can approach the JOHN BULL DEEP DRIVE—

We know, because we've seen and tested the others and—if you've done the same we think we know the belt you use to-day—it's the

**JOHN BULL**

—the belt with wonderful gripping power—a merit entirely worthy of its name, a merit created by its unique construction—deeper sides and a registered raised top which ensures their full utilization and 15% to 33% more driving surface than is usual.

And there are many other points just as valuable—so ask your Agent about it.

# MISCELLANEOUS ADVERTISEMENTS.

## PRICES.

**ADVERTISEMENTS** in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to **ILIFFE & SONS Ltd., and crossed** & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

## NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

## DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

## SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

## DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

# DRUID

## Shock Absorption

The power of the DRUID MARK II. Spring Fork to totally absorb ALL shocks incidental to "bad roads" — and the lively sense of SECURITY and COMFORT necessarily imbuing the rider of the DRUID-equipped machine — are primarily

## Due to the DRUID dual springs

These admittedly stand as the foremost expression of scientific Fork design — the upper Horizontal member operating in perfect unison with the lower Vertical member (as shown below), together to absorb all vibration within the Fork itself.

The judgment of "Experience" is unanimously in favour of the DRUID — so complete, so dependable, and — so lasting.

Ask for full details.

**A. Drew & Co. Ltd.**

**1915-16** 3½ h.p. Sunbeam Combination, as new, fully equipped, sell separately, absolutely perfect; £67.—59, Station Rd., Landaff North. [X2074]

**1915** 3½ h.p. 3-speed Sunbeam Combination, fully equipped, excellent condition; £80: cash or easy terms.—R. E. Jones (Garages), Ltd., Swansea. [0862]

**6** h.p. Sunbeam (Oct., 1914), and coach-built sidecar, splendid condition; £70; Douglas lightweight part.—P. Hemingway, Redvers House, Stanley, Wakefield. [X2072]

**1915** 6 h.p. Sunbeam Combination, Gloria de Luxe 5 gns. sidecar, fully equipped, done 5,000, all as new; cost £150, quick sale £75; after 6 p.m.—24, Tudor Gardens, Barnes. [4791]

**1916** 3½ h.p. Sunbeam, black-gold, 3-speed, hand-controller, clutch, semi-T.T. bars, complete with lamp, about 1,000 miles only; £76.—Robinson's Garage, Green St., Cambridge. [4660]

## INCREASED PREMISES.

Owing to the large increase in our Business, we have been compelled to open large new Show-rooms and Garage at **31, High Street, Hampstead**, in addition to our present premises. We have now every facility for continuing to accept Machines and Light Cars for Sale on Commission, at 5% inclusive—no sale, no charge—and are increasing our business in all directions. Customers will find a still better selection of Cars and Motor Cycles, of which the following are a selection from the 150 in stock:

<b>ENFIELD</b> 1916 Combination, mileage under 1,000, as new	82 gns.
<b>ENFIELD</b> , 1915, 3 h.p., 2-speed	32 gns.
<b>ENFIELD</b> , 1916, 2-speed, 2-stroke	29 gns.
<b>ENFIELD</b> , 1913, 2-speed, clutch, 2½ h.p.	24 gns.
<b>RUDGE-MULTI</b> , 1913, wide tank	26 gns.
<b>RUDGE</b> , T.T. Philipson, 1913	22 gns.
<b>ZENITH-GRADUA</b> , 1915, 4 h.p., twin, countershaft, red finish	39 gns.
<b>B.S.A.</b> , 1913, T.T. 2-speed, clutch	29 gns.
<b>CALTHORPE-J.A.P.</b> , 1915, 2-sp., clutch	19 gns.
<b>DOUGLAS</b> , 1913, T.T. 2-speed	29 gns.
<b>DOUGLAS</b> , 1914, T.T. 2-speed	32 gns.
<b>DOUGLAS</b> , 1915, T.T. 3-speed	37 gns.
<b>GRANDEX-PRECISION</b> , 1917, T.T. 4 h.p., brand new	29 gns.
<b>HARLEY-DAVIDSON</b> , 1915, Combination	65 gns.
<b>HARLEY-DAVIDSON</b> , 1916, Combination	79 gns.
<b>NORTON</b> , 1914, T.T. Philipson	33 gns.
<b>NORTON</b> , 1915, T.T. Philipson	37 gns.
<b>PREMIER</b> , 1914, 3½ h.p., 3-sp., clutch, kick-start, Canoelet Sidecar	39 gns.

## CARS.

<b>MORRIS-OXFORD</b> , 1913, re-painted, overhauled	109 gns.
<b>BELSIZE</b> , 1913, 10-12 h.p., light 4-seater	169 gns.
<b>CARDEN MONOCAR</b> , 1915, 4½ h.p., twin J.A.P.	42 gns.
<b>G.N.</b> , 1914, 2-speed, with 8 h.p. o.h.v. Buckingham engine	39 gns.

## Motor Cyclists in the Army.

SOME months ago we mentioned the case of a despatch rider Overseas who, originally enlisting at the rate of pay of 5s. per day, was reduced to 3s., the reduction applying retrospectively, and so far affecting his remuneration that it was found the despatch rider owed the Government a matter of £84 odd for overpay. His pay, therefore, was to be entirely stopped until this considerable amount was made good. The case was exposed, and complaints lodged by the recruit's father—who, incidentally, is a J.P.—led to a satisfactory letter from the R.E. explaining that the matter had been adjusted, and quite rightly too. The letter went on to point out that the ordinary rate of pay applying to despatch riders would be the rule from January 8th, 1917—a decision which is not at all popular among men who responded to the early appeals for despatch riders at 5s. per day.

Last week we received a letter from a despatch rider in Mesopotamia, protesting against the treatment of the D.R. to whom we have referred (he had not at the time seen the development of the position), and urging vigorous action and restoration to the rate of pay sanctioned and in effect at the date of enlistment. It has already been made clear that 5s. per day was the official rate laid down at the commencement of the war, and despatch riders were invited to enlist at this rate of pay. A month or two later the figure was reduced to 3s., so that it will be seen that only the very earliest recruits have been affected by the reduction of pay.

## Varying Rates of Pay.

Another matter brought to light by the same writer again concerns the subject of pay of despatch riders, and is the cause of much consternation among men in Mesopotamia. Motor cyclist reinforcements are sent to that country from India and Egypt as well as from England, and on arrival at the base are detailed to join

different units up country. Those riders fortunate enough to be attached to an Indian unit are entitled to receive 3 rupees 2 annas per day; others less lucky, detailed to join an English unit, are paid at the British rate of 3s. This is almost as bad as paying (as was done in the early days of the war) 6s. per day for the comparatively safe job of driving a car in the Transport Section, and 1s. per day for service in the trenches. Could anything be more unfair? Our informant goes on to say that a call is made upon infantry units in India to send desirable men for training as despatch riders. When passed for this duty and proceeding on service they receive 3 rupees 2 annas per day, irrespective of the unit they join; thus it is no uncommon thing to see men newly trained, in most cases having seen no active service, working side by side with experienced motor cyclists having 2½ years of service to their credit, and who are receiving approximately 1s. 2d. per day less than the new arrivals.

It is high time that the matters outlined were officially investigated. Too much luck and not enough merit seems to enter into the question of pay. At any rate, it is an absurd position for motor cyclists on precisely similar duties to receive varying rates of pay. Many motor cyclists are still receiving 6s. per day in the A.S.C., others get 5s. in the R.E., and latterly 2s. 6d. plus 6d. In the R.F.C. a motor cyclist receives 2s. per day, and new recruits in the M.T. get 1s. 2d. per day, rising to 2s. 4d. when proficient. 1s. 2½d. is the pay of men in the M.G.C., and many motor cyclists who are fighting in line regiments get actually less. Ordinary people cannot understand these variations of pay. In 1915 a question was asked in Parliament, and the explanation was to the effect that the rate of pay depended upon the section to which a man belonged. That "explanation" satisfied M.P.'s apparently, but every motor cyclist knew as much beforehand, and therefore was no wiser.

## SIDECAR EQUIPMENT.

A 1917 Model Outfit of Luxury which Cost £160.

The Owner's Appreciation.

A Harley-Davidson owned by Mr. Ernest B. Allport, of Birmingham, to which almost every refinement in the way of accessories has been added. The finely finished sidecar is not a standard H.D., but was made by Messrs. F. Cooper & Co.

**D**ESPITE the prohibition upon the import of foreign-made motor cycles, a certain number of 1917 Harley-Davidson machines have found their way to this country. These machines, it may be observed, were permitted to be imported by reason of the fact that the company's stock was hurriedly exhausted on one occasion to satisfy military requirements. For one thing the Harley-Davidson Co.'s readiness to give up its stock of 1916 models was, from one point of view, a boon to motor cyclists, since it has enabled motor cyclists at home to sample America's best. There cannot be many specimens of the 1917 model in Great Britain, but golden opinions reach us from users. Green drab is the distinctive finish of the new model, so that readers can readily recognise it on the road. Certainly one of the finest examples we

have seen is that owned by Ernest B. Allport, of Birmingham, whose mount, fitted with a Remy electric generator lighting-set and a special sidecar produced by Messrs. F. Cooper and Co., Belgrave Road, Birmingham, is replete with every modern accessory, its total cost being £160—surely a record for a sidecar outfit. In writing to us concerning his new acquisition, Mr. Allport says:

### Electric Equipment.

"Before owning the Harley-Davidson I had a 1916 model B.S.A. with Gloria sidecar. This outfit I exchanged through Mr. Allerton, of the Colmore Depot, for a new Harley-Davidson model 17J. The very complete electrical outfit attracted me, a magneto-generator with electric head lamp, tail lamp, plug for inspection or sidecar lamp, in conjunction with an

electric horn, promised to provide the utmost convenience on night runs, and I am pleased to report that up to the present the lighting system has given perfect satisfaction. The question of lubrication, too, I find can be banished from one's mind. One has simply to replenish the tank when it is empty, and the rest can be left to the mechanically-operated pump.

### The Result of a Slipping Clutch.

"Petrol consumption with such a powerful machine and heavy sidecar is not light, and I find averages 50 m.p.g. for ordinary town running. Still, this is a distinct saving of precious spirit when compared with a car at anything like the figure my sidecar cost. I find I can handle the Harley with the greatest ease, thanks to the clutch, which seems to be everything that can be desired. All the same, I recall one singular experience with the clutch; it happened some weeks ago in Coventry. I had been running for some miles with the clutch slipping badly, but being a novice and not knowing how to adjust the clutch I had to continue into Coventry the best way I could. After stopping to make my business call I returned to the machine and found it an impossibility to restart. After inspection I found I had burnt the clutch lining out.

"This sounded to me an awkward business, so I decided to leave the machine in Coventry for the night, and next morning visited the Colmore Depot in Birmingham. The people in charge promptly sent over a mechanic who adjusted the clutch, and we were on our way back to Birmingham in less than ten minutes.

"As regards comfort I find the Harley as satisfactory as anything I could wish for—thanks to the big wheels and big tyres, and the saddle springing.

"After 1,500 miles on my new Harley I am a delighted owner, and have no reason to doubt that my future experience will be in any way less satisfactory than hitherto."

Many people show surprise when told that the cost of this outfit was £160 and compare it with the cost of a light car. The outstanding attraction of such a combination is the pleasure derived from possessing the very finest of a type comparable in the finish of its mechanical parts, coachwork, and accessories with the most expensive car, to say nothing of its speed capabilities.

BY LION

## Getting the Wind Up.

OLD campaigner as I am now, I sometimes get the wind up about sideslip. The required conditions are a dark night, a poor lamp, an unknown road, and the brands of grease which limestone and oolite generate when they are about half dry. I peer into the gloom, I wonder whether I have taken a wrong turn, I drive timidly and jerkily: finally, I realise that my back wheel is not adhering very tenaciously, that my front wheel will lie down sideways at slight provocation, that the road is extremely hard, that my overalls are new, that Gladys will not embrace me with her usual abandon if I am miry from head to foot, and that my knees, elbows, shoulders, and knuckles bear many old scars. In about five minutes after these cogitations are complete, my wrists lose their vice-like, masterful grip: the little U tubes behind my ears cease to register balance subconsciously as they should, and long-forgotten swearwords snarl unbidden through my clenched teeth as the bicycle takes charge. By this time I am awake to the situation. I change gear downwards: the smooth purr of the accelerating exhaust suggests that the back wheel is biting earnestly into the road: confidence returns, and I drive rather faster than before.

## The U Tubes.

NO; I don't mean "U boats," gentle reader. The last time I went to a lecture on aviation I woke up, after half an hour's machine gun fire of logarithms from the professor in charge, to catch an interesting statement about the personal factor in pilots. Forty winks over my shorthand pad lost me his opening remarks; but, in effect, he said that every man had a pair of little U shaped tubes behind his ears, which gave him his sense of equilibrium. I didn't quite catch whether they were filled with mucus, or mercury, or blood; but, anyhow, some sloppy, human stuff or other perpetually tiptilts to and fro in them as your body sways around the vertical, and the resulting pressure informs your brain that you have stepped on a banana skin, or are towering in righteous rage above that fool Jones, as the case may be. To ascertain what condition these tubes are in, you simply shut both eyes and stand on one leg. If you can do this for two minutes without toppling against the sharp corner of the ancestral marble mantelpiece your U tubes are O.K. If you can't, they are afflicted by catarrh, or need grinding in, or remagnetising, or something. Well, presumably, the man who can ride a motor bicycle with a flat back tyre is the lucky possessor of a pair of perfect U tubes with jewelled mountings; and the man who sideslips on a new Triumph as soon as it begins to rain ought to get his U tubes blown out from a steam

jet, or receive other suitable medical attention. Now I have offered you two tests of your anti-sideslip efficiency—one for the road, the other for the parlour. Try them both, and if you fail in either you can see it is not much use buying that expensive steel-studded tyre you had in mind for next winter.

## A Ludicrous Phenomenon.

MR. DAVID SHARP has at last produced a plausible explanation of my puzzling case, so far as the periodic misfiring on the flat is concerned. It is fairly obvious that a silencer which caused excessive back pressure would choke the engine down exactly after the fashion of an exhaust valve which failed to open fully. The burnt charge would not be cleared properly, a full charge of fresh gas could not be inhaled: the explosions would sound muffled, and would fall off in power. As soon as the congestion in the silencer was relieved by the gas pressure seeking the only available outlet, an increased charge could be inhaled, the explosions would recover in power temporarily, fresh congestion would pile up in the silencer, and the series would recommence *ad lib.* or *ad nauseam*. But I do not quite see how Mr. Sharp's otherwise plausible theory accounts for the fact that, in each case reported to me, the misfiring disappeared absolutely when the machine encountered a hill. Off-hand, one would suggest that two errors of design exist in combination: and that the faulty silencer only accounts for half the symptoms. I do not know the particular engine concerned, and must leave it to owners to hammer the whole matter out fully.

## Machine Guns and Motor Cycles.

OUR publishers have broken out in a new spot by issuing a handbook on the Hotchkiss gun, which reminds me that thousands of our readers have found the knowledge gained from the "Blue 'Un" and its associated manuals invaluable in mastering a weapon which is even more lethal than the motor cycle, to wit, the machine gun. During their apprenticeship to the machine gun they are often heard to sigh for the simplicity of the motor cycle. Whatever accusations can be brought against the petrol engine, it keeps its strokes separate and distinct, and you can learn them and their significance one by one. Now the machine gun, by contrast, is a hoary deceiver. It poses as a two-stroke—one stroke backwards, and one forwards. Your heart warms to it, but you gradually discover that each stroke consists of about umpteen separate actions, which are perpetually overlapping and interfering with each other. Anyhow, it is some machine. The lock of the Vickers and the pawls of the Lewis are alleged to have sent more than one expert Brooklands tuner into a lunatic asylum.

# ALUMINIUM AND AIR-COOLING.

## THE EFFORTS OF THREE COVENTRY MOTOR ENGINEERS.

**L**AST week we published an article in which for the first time, so far as we are aware, an endeavour had been made to establish the originator of the use of aluminium as a cooling medium for cylinders. In that article we described how recent efforts by one would-be patentee—a motor cyclist incidentally—had brought to light the existence of a patent of 1898 standing in the name of Robert Ayton, of Coventry, another motor cyclist. This patent, as we showed, expired before the advantages of the use of a metal of high heat conductivity were appreciated—indeed, many motor manufacturers have still to appreciate the fact. Since the use of aluminium is bound to grow rapidly, in our judgment, we devote further space to this engrossing subject.

In the accompanying notes Mr. R. Ayton—whom we traced to the R.N.A.S., in which section he is a chief petty officer—replies to our letter of congratulation upon his early realisation of the properties of aluminium and its likely use upon motor cycle engines. After expressing appreciation of our "friendly enthusiasm," he says:

"In my opinion, you are quite right in backing the principle as full of promise. To me it is a link in a well-defined chain of progress. Water-cooling for aircraft engines may, I think, be safely regarded as doomed to ultimate extinction, in company with those moribund but useful stop-gaps or makeshifts, the rotary and fixed cylinder radial types of engines.

"In order that you may be in full possession of all the known facts, I send you a copy of the only document in which the use of aluminium is referred to as a material for cylinder-cooling fins. This is in the form of a specification by our old friend E. J. Pennington—no less. It is very clear that he only suggested aluminium as a possible material on account of its ductility—in fact, the amusing remark in lines twenty-eight to thirty:

Or again, the gills may be cast complete with a suitable flange or fastening device, say in two halves or even as a complete tube to fit outside the cylinder, *but as this would tend to retain the heat* I prefer to make the gills or their fastenings in skeleton form and attach them to the cylinder in the simplest manner

C.P.O. Robert Ayton, R.N.A.S., who in 1898 obtained a patent for cylinder jackets composed of metal of high heat conductivity.

## ROBERT AYTON'S IMPRESSIONS.

### E. J. PENNINGTON'S SPECIFICATION OF 1897.

shows that Mr. Pennington was innocent of any idea of the physical properties of what he was handling. He omits all mention of it from his 'final' and claims.

"Did he ever use these flanges on his few completed engines? His cylinders, as I seem to remember them, were essentially 'simple steel tubes turned up' (quotation from actual patent), and, in the gloaming on the Kenilworth Road, invariably glowed like the business end of a very large cigar.

The cottagers along his usual routes were said to derive a comfortable income from the supply of buckets of water—sort of cooling relay, as it were.

### A Recent Discovery.

"I may say that I was quite unaware of the existence of this patent of Pennington's until about four or five years ago, yet he must have lodged his application at the very time that I was burning my fingers in verifying the fact that one of the principal causes of the failure of certain aluminium-soldering attempts lay really, not in the flux or the solder, so much as in the remarkable rapidity with which the heat appeared to be drawn along the metal away from the 'bits' used. This was, I believe, at the time (circa 1897) that I was acting as assistant to W. A. Taylor, then works manager of the New Beeston Motor Co., Ltd. Taking this observation as a starting point, you will readily understand the use to which I naturally sought to put such a curious property, and my specification becomes self-explanatory.

"I built several engines of this type during the period of 1898-1902, mostly single-cylindered of 4in. bore x 7in. stroke. The fins were extended and bored for the passage of the frame tubes as shown in the photograph.

"This arrangement not only provided a light, strong, and rigid support, but provided a rapid and successful means of varying the compression—an important point in those days of tube ignition. The larger tank is the surface carburetter, fitted internally with eight wick cotton screens and a float-controlled air admission device. The smaller reservoir is the pressure tank supplying the Bunsen burner. Induction pipe and chamber, balance weights and valve gear, etc., are omitted.

"These engines were immediately and uniformly successful, ultimate failure of the first

One of the several engines built by R. Ayton between 1898-1900, having an aluminium jacket over the cylinder barrel. The fins were extended and bored for the passage of the frame tubes.

Unrivalled in excellence of construction and in efficiency of road service, there is no rival to Ariel Reliability—no challenger to dispute its reliability sovereignty.

**Aluminium and Air-cooling.—**

one after about three years' hard work being due to breakage of the frame tubes at the plumber blocks. During this period there was never even a momentary failure due to inadequate cooling. *But—* It is written that there are two kinds of success—*le succès d'estime*, and the *succès d'exécution*. This device certainly attained the latter. Of the many firms—British and Continental—to whom it was offered, only one of the former would even take the trouble to examine and try it. That honourable exception was the Daimler Co., whose (then) managing director and chief engineer—I think the latter's name was Blake or Drake; that of the managing director was, I believe, Foster Pedley—accepted my invitation to try and 'race' the engine to a standstill in a closed apartment. I forget how many pipes we smoked between the three of us whilst waiting for the engine to seize up. She was 'glumphing' along at a steady 960 r.p.m. unloaded, full throttle and retarded ignition, so just imagine the atmosphere of that closed workshop—20ft. x 9ft., about! Radiation? Why the A.I.R. was almost as hot as the jacket before we had finished. Try it some time! I rather enjoyed it, for I had 'been over the course' several times before, and I knew the cooling wouldn't let me down. Nor did it. They got tired first. In the end I received a congratulatory letter, but the company would not take it up.

**Absence of Valve Pitting.**

"One of the most remarkable features of these engines was the absence of valve pitting, in spite of a lot of such use—or abuse—as above.

"A smaller (vertical) two-cylinder was subsequently converted to a two-stroke, and gave results which fully justified the novel design I had in hand when war broke out.

"But to hark back. It is a fact that one of the alternative fittings which I originally contemplated is the full length screwed one now employed in the Hispano-Suiza aircraft engine. I rejected it as being: (a) too dependent upon the absolute accuracy of lead screw and lathe bed, and in view of (b) the high coefficient of friction in aluminium, which in order to avoid 'gripping' in midfit in such a length, would necessitate such an 'easy fit' between liner and jacket as largely to nullify the effect of the (theoretically) extended contact surfaces.

"In the engine shown in the photograph, the jacket was cast on before the bore was finished out; just as in the aircraft engines now made for the Government by a firm that about 1902 turned down my 'flat twin' design embodying this principle. In the two previous examples (including the one tested as before related) the jacket was bored taper to correspond with the coned exterior of liner, heated, and forced up into position by a screwed ring nut on the liner nose; this entailed rather greater cost of machining, but the system proved quite satisfactory.

"Only in an engine with a high conductivity jacket have I found it possible to secure the full benefits

of a denaturised alcohol fuel, and I may be permitted to remark that the highest practical results yet attained with such a fuel are those recorded in this journal under date 12th September, 1906, as the results of joint trials by the Editors of *The Motor Cycle* and *The Autocar* in collaboration. Such a fuel—the permanent product of a hitherto undescribed reaction—must ultimately come into general use, in spite of the obstructive attitude of the Excise authorities and of the petroleum interests. The details of its preparation are—as ever—at the disposal of the nation whenever there is a reasonable prospect of supply to the public being facilitated.

"One factor in the realisation of maximum weight efficiency from any type of engine using any kind of liquid fuel is the employment of *absolutely* synchronised multi-point ignition. This implies the employment of a number of firing points in series upon one circuit, without reference to the type of apparatus employed. This principle was first described by me in Patent 23,810 of 1906, and I have been described in the columns of *The Autocar* and *The Motor Cycle* (I believe correctly) as the originator of the theory upon which this practice is based, which

now receives extended practical application year by year. It is particularly advantageous with an alcohol fuel, so that you have here, clearly displayed, the inter-relation of three of the principal original features of my work. Of the further (related) items now in hand, it is too early to speak."

In the foregoing remarks, which we are confident will be studied with interest by students of design, Mr. Ayton refers to a patent specification by Mr. E. J. Pennington; it is numbered 4,556, A.D. 1897. An extract is quoted from the provisional specification, and we repeat *in extenso* the complete specification,

and also reproduce the drawing referred to:

**COMPLETE SPECIFICATION.****Improvements in or relating to the Cooling of Cylinders of Explosion Engines.**

I, Edward Joel Pennington, of the Motor Mills, Coventry, in the county of Warwick, engineer, do hereby declare the nature of this invention, and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:

This invention relates to the cooling of the cylinders of explosion engines, and may be carried out in the following manner:

I provide the cylinder externally with detachable radiating plates or gills, of which the accompanying drawing is a perspective view partly broken away, showing four of the detachable gills in place upon the cylinder of an engine.

Each gill A is shown separate from its neighbours, and is either a complete ring or divided into two parts as shown in the drawings. Or the gills may be all cast or otherwise formed together and held to the cylinder together. A flange B is provided, and lugs C are formed on each half of the gill so that the two parts may be clamped around the cylinder by screws D, the position of the cylinder being indicated in the drawing by dotted lines.

The gills may be made of ductile metal, such, for example, as aluminium or gun metal, so that they can be easily bent to fit the cylinder, and they or their flanges may be run into dove-tail grooves formed in or upon the cylinder.

An early patent by Mr. E. J. Pennington, which relates to the cooling of cylinders by means of detachable radiating fins. The drawing is from a specification dated 1897.

**Aluminium and Air-cooling.—**

If desired the flanges B may be bolted direct to the cylinder, or other means than those shown may be employed for detachably fixing the gills upon the cylinder.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:

1. A detachable plate or gill substantially as and for the purpose described.

2. The combination with an explosion engine cylinder of detachable plates or gills substantially as and for the purpose described.

Dated this 4th day of June, 1937.

E. J. PENNINGTON,

By his Attorney, John Bradley Carse.

Boult and Wade,  
Agents for the Applicant.

## HEATING THE FLOAT CHAMBER.

FROM time to time we have illustrated suggestions for heating the float chamber to assist vaporisation. There is much to be said in favour of this method, by which the temperature of the fuel is raised considerably before it is sprayed through the jet, but the benefit thus derived is counteracted to some extent by long induction pipes which tend to cool the mixture before it reaches the cylinder. This difficulty can be overcome by lagging the induction pipe with asbestos cord. As regards jacketing the float chamber, our contributors' ideas have generally consisted of a simple tin cover designed to surround the chamber with copper tubing connections to the exhaust.

The Grado Mfg. Co., of Pershore Street, Birmingham, have introduced a substantial and easily adapted fitment for float chamber heating. It takes

Grado  
float chamber  
jacket.

the form of a neat polished aluminium casting with lugs drilled to take inlet and outlet pipes. Packing glands at top and bottom ensure tight joints between the jacket and the carburettor body. Several types are to be made to suit the chief makes of carburetters, the fitment we illustrate being for an Amac. A length of tubing and clip for connecting to the exhaust will be included. This addition is of the highly desirable kind that any motor cyclist can fix to his carburettor in a short time, and it should remove many heavy fuel difficulties. The Grado paraffin vaporiser, which has been on the market for some time, is now issued in a simplified form, certain internal alterations having been

made. Its price is now 35s.; a larger type, but of similar construction, is made to suit light motor cars and Fords.

## HANDLE-BAR CONTROLS.

THE matter discussed by "The Critics" last week points towards the desirability of a general revision of handle-bar controls. We know of many riders who, though appreciating the enormous advantages of the handle-bar clutch lever, still favour the pedal operation on the grounds that they already have enough stuff on the handle-bars.

Recently we were examining an experimental machine on which both brakes are foot-operated, and placed respectively to the right and left foot of the rider. The drawbacks to this system are, firstly, that a front wheel brake, unless delicately applied, is more of a danger than a safeguard, and the nervous rider who "plonked" his foot hard on the pedal would most assuredly come to grief. Then, if both brakes are transferred to the back wheel, the object of having two of them is defeated, for the primary object of the front brake is for applying that slight extra braking effect which is to prevent the rear wheel from skidding, the maximum braking effect being at the moment when the rear wheel is almost skidding.

We have had instances of the foot-operated ignition control, perhaps not entirely happy, but the three levers which load up the bars are the clutch, which must remain where it is, the exhaust valve lifter, and the front wheel brake. There is no reason why the two latter should not, by a very simple mechanism, be interconnected, the first movement of the lever raising the valve, and a further movement applying the front wheel brake, which, after all, is seldom used, and at all events only when the engine is not required—on descending long hills, for instance.

Our experience of interconnected controls has not, perhaps, been very rosy in the past, but things are better made to-day, and the arrangement suggested might, at any rate, mean one Bowden cable less, while it would enable us to dispense with one rather useless lever, so that the rider would have but two—one on either hand: Several modern machines have combined hand and pedal control for the clutch, which system has much in its favour, and the practice is likely to grow.

**J**UST an extract from one of the hundreds of letters we receive from Despatch Riders using Triumph Motor Cycles on active service :

“The way the Triumph sticks it over these rough roads, and in winter through the terrible mud, speaks most highly of the good workmanship and high-class material used in the construction of Triumph Motor Cycles. Never is a D.R. more confident of delivering his messages, and returning safely, than when mounted on a

## MILITARY NOTES.

### WITH THE MOTOR BOAT PATROL.

THE subject of the accompanying photograph is C. M.-M. W. Moore, who is with the Motor Boat Patrol in the Eastern Mediterranean. Moore is a motor cyclist, and has just been promoted to chief motor mechanic after sixteen months' service. Prior to enlisting he was employed by Zenith Motors,

Chief Motor-mechanic W. Moore, of the Motor Boat Patrol. His mount is a twin Zenith-Gradua.

Ltd., Weybridge, and in the photograph he is seen astride his 1915 model 4.5 h.p. Zenith, which naturally he misses very much. Last week Moore wrote to his father, mentioning how eagerly they look forward every mail day for the copy of *The Motor Cycle* which his father posts to him regularly.

### D.R.'s "IN FRONT" AND "BEHIND."

CPL. H. E. B. GOATER, writing from the Central Military Hospital, Aylesbury, confirms the statements we have made respecting the dangers run by D.R.'s. It is quite clear that there is a vast difference in the security of the various D.R. staffs, those of the Divisional Brigade Artillery coming in for their full share of trouble.

"The photograph I enclose was taken in a French village about three miles from the German trenches. As you will see, the machine is a good old trusty Triumph and heavily coated with mud.

You can imagine from its appearance the awful state of the roads and riding conditions in the fighting area in France. One could hardly have imagined the rough usage a motor cycle gets whilst running over the shelled and pot-holed roads between Brigade and Divisional Headquarters. This machine I took to France with me in the early part of 1915, and it served me faithfully without any trouble.

"With regard to casualties amongst D.R.'s. Of course only Divisional Brigade and Artillery D.R.'s work entirely in the danger zone, and even their exciting experiences are usually confined to the period when a big battle is in progress. The staff of D.R.'s on divisions and brigades is very small, as you know. All the other D.R.'s, and there are thousands of them, have more or less 'cushy' jobs miles behind the line, where they practically live in peace, and are as safe as if living in London. Some of them may be worked hard, but their life is much easier than when training in England.

"I would add that our original staff of Divisional Brigade D.R.'s were all old boys who enlisted during the first few weeks of the war, and a fine set of boys they were, too (real sports, every one of them). Unfortunately during the Loos battle, in September, 1915, my chum, Cpl. Essex, who was on Brigade Headquarters with me, was killed, so also was Cpl. Howes, another of our brigade men, whilst Cpl. Bill, of our brigade, also was badly gassed. Our luck was out, and that was the beginning of the breaking up of a happy band of D.R.'s. Since that time several of them have obtained commissions in the R.E., R.F.C., Tanks, etc., and I believe there are only two of the old boys left at the Division."

### THE THOROUGH HUN.

QUITE recently we mentioned that F. J. Watson, an M.C.C. member, who has performed conspicuously in the leading competitions mounted on Ariel motor cycles, had joined the Royal Flying Corps as second air mechanic. The other day we were advised that he is in hospital, his trouble being due to an extraordinary experience, which once again shows how thorough the Huns are in their black deeds. Watson had been dismantling a Mercedes engine—one of two having six cylinders, 160 mm. bore x 180 mm. stroke—mounted in a German battleplane brought down in France. The engine was started by a decompressor actuated by a sliding camshaft on the cylinder heads, bringing the decompressor cam into operation on the exhaust valves, as in the Ariel motor cycle engine. After Watson had been at work on the engine for a day or two the palms of his hands turned a vivid yellow, followed by a skin disease, which gave trouble for over three weeks. Only the palms of the hands changed colour, so it could not have been due to the oil. Watson considers himself extremely lucky to get off so lightly. His experience might have been a good deal worse but for the fact that the engine had been on fire, which would no doubt destroy most of the strength of the preparation on the engine, whatever it may have been. By the way, the engine above referred to has four valves per cylinder—two exhaust and two inlet—whilst the connecting rods have floating small-end bushes. Another unusual feature is the piston design; the latter are made in two parts, the piston wall being screwed to the head and welded over.

Cpl. H. E. B. Goater, R.E., who enlisted as a despatch rider early in the war, and has been through strenuous times on the Western Front.

## War-scarred Motor Cycles.

The British Red Cross Society offered for sale in our last issue a number of Rudge motor cycles returned from foreign service. Already the same society has disposed of many war-worn cars.

## Change of Address.

We have heard from the Secretary, Mr. Horace Wyatt, of the Association of British Motor and Allied Manufacturers, Ltd., to the effect that the War Office has found it necessary to commandeer his present office, and that future correspondence should be addressed to 39, St. James's Street, London, S.W.1.

## Holiday Employment for School Boys.

A public school boy, who hitherto has spent his holidays motor ploughing, but who evidently finds this rather dull, asks whether the R.F.C. can find temporary employment for school boys on vacation as despatch riders or car drivers. We have advised him to stick to ploughing, though we certainly think that organised measures might be taken to utilise the schoolboy to the best effect.

## Advertising Second-hand Machines.

A reader writes us: "May I suggest that advertisers of second-hand machines be advised to give full particulars and price of their machines, in order to save would-be purchasers trouble and expense? For instance, in a recent issue appeared an advertisement of a Royal Enfield sidecar, neither year nor price being given, but stated to be in new condition. I went to see this machine (this took a whole morning and entailed a walk of a mile and a half); when I arrived I found, although in excellent condition, the price asked for the outfit was the fabulous and ridiculous sum of £75, and it was a 1914 model. Had the year and price been stated in the advertisement I should naturally not have given it a second thought. I could also quote three other instances nearly as annoying." We fully agree with our correspondent's sensible suggestion, and we would further point out that many would-be purchasers do not trouble to investigate an offer if the date of machine is omitted. Many a good machine goes begging owing to lack of important detail in the advertisements.

## London Motor Volunteers Wanted.

We have been asked by the A.C.U. to state that they have been requested by the City of London Motor Volunteers (4th-23rd squadrons) to appeal for sidecar owners, who are urgently required as recruits. Petrol used on duty is supplied free. Applications should be addressed to Mr. A. Wright, 12, Bathurst Street, W.2.

## Race Meetings and Motor Vehicles.

That horse racing is to be allowed to continue to a limited extent is not, of course, novel news, but in a letter to the senior steward of the Jockey Club Sir Albert Stanley makes clear that suitable measures are to be taken for limit-

## SPECIAL FEATURES.

MORE SPORTING REMINISCENCES.  
ALUMINIUM AND AIR-COOLING.  
A REJUVENATED MORGAN.

ing the amount of traffic to and from the race meetings. The railway companies will not provide special trains for race-goers, and, owing to the shortage of petrol, no motor vehicles are to be used in connection with the meetings—or, rather, those who attempt to use motor vehicles will probably be called upon to forfeit their licences as a result. This is entirely in accordance with the proper order of things, against which no true sportsman can complain.

## SOUTH AFRICAN RECORD-BREAKERS.

The Johannesburg-Durban record attracts great attention in South Africa, and in some ways this now famous run may be compared to the historical Land's End-John-o'-Groat's route, which in England formerly held a similar interest for record-breakers. Some time ago the African sidecar record was broken by Enfield riders. Messrs. Bright and Keag, whose photograph we reproduce, covered the 420 miles separating the two cities in 14 hrs. 12 mins. The previous record stood at 14 hrs. 50 mins. The appearance of the riders and their 6 h.p. Enfield gives some indication of the strenuous nature of the trip.

**The National War Funds.**

At the week-end the principal relief funds stood as follow:

The National Relief Fund (distributed £3,641,622) .. ..	£6,213,333	0	0
British Red Cross Fund .. ..	7,072,574	10	7
Tobacco Fund .. ..	132,508	0	0

**Inspector of Petrol Consumption.**

It was recently announced in the *London Gazette* that Col. (temp. Brig.-Gen.) Sir C. W. King, C.B., M.V.O., has been appointed Inspector of Petrol Consumption.

**A Practical Driver.**

If every private owner took the same care of his machine as the owner of the Morgan Runabout referred to in this issue, second-hand prices might be higher still. Illustrations of a number of the improvements effected accompany the descriptive matter.

**Police Hunt for Military Sidecar.**

Police in the S.E. of London are searching for a dark-coloured low-built sidecar which it is alleged knocked down a private of the A.S.C., M.T., at Beckenham Lane, and did not stop. Both driver and passenger were soldiers. The injured man has died in hospital. It was dark at the time.

**Is a Shock Absorber Necessary?**

Recently we tried a big all-chain single, in the transmission of which no shock absorber is included. Owing to low compression and large flywheels no snatch was detectable even at very low speeds, but if the gears or the clutch were roughly handled a terrific snatch was apt to result. Certainly, for the average rider, a shock absorber is desirable for this type of machine.

**Good Opening after the War.**

There should be a good opening in agricultural circles after the war for capable mechanics having some knowledge of internal combustion engines. The use of petrol and paraffin-driven machinery on farms has increased since 1914 to an extent not generally realised. In addition to motor ploughs and tractors, portable petrol engines are now used on almost every farm, and a few days ago we visited a place where 160 cows are milked morning and night—by machinery! The machine is similar to an exaggerated vacuum-cleaner, and does the work of a whole retinue of herdsmen.

**Wastage of War.**

Thirteen Rudge Multi motor cycles offered for sale by the British Red Cross Society form a rather interesting collection. These machines, we are informed, were some of the old stagers of the 1914 campaign, and from their appearance one can quite believe it. Out of the thirteen there is only one in a really rideable condition. All are minus belts, and most of the tyres are flat. Two we noticed had only half a handle-bar, one was without cylinder and piston, some were without magnetos, and one we particularly noticed could hardly be described as a motor cycle, as only the frame and head stem remained. They are all plentifully besprinkled with Flanders mud and very rusty, which cannot be wondered at, as we understand that for the first nine months of their career they were garaged in the open and did not see a cleaning rag during the whole period.

**Still Short of Petrol.**

Shortage of supplies prevents the suggestion of petrol for munition workers' holidays being carried into effect. A letter on the subject appears in our correspondence pages.

**The Originator of Aluminium Cooling.**

*The Motor Cycle*, having tracked down the originator of aluminium as a cooling medium for air-cooled engines, is able this week to publish the views of the patentee. C.P.O. Ayton has seen no direct benefit from his early recognition of the usefulness of aluminium for the purpose named, as he was before his time, the patent he held expiring before the advantages of the system he protected became recognised.

**A Convert.**

When a few days ago an experienced rider of high-powered machines, who has long scoffed at the baby two-stroke, was compelled to undertake a sixty-mile journey on one of these diminutive machines, we awaited with interest his comments. He confessed himself utterly surprised at the capabilities of the little mount, and is now to be seen daily using it as a business hack. We have a shrewd suspicion he has bought it!

**Spanish-built Cycle Cars.**

There seems to be quite a boom in cycle cars in Spain, one make—the David—being produced in fair quantities. In view of the state of Spanish roads it will be interesting to observe their performances after a twelvemonth existence. We acknowledge that many defects of the early cycle cars produced in this country have been eliminated, so that there is a reasonable chance of success.

**The Cycle and Motor Trades Benevolent Fund.**

The hon. treasurer's report at the last meeting showed that for the first eight months of the current financial year the expenditure on relief and administration had been £2,234, as against £1,799 for the corresponding period of last year. Not only had the number of applications for relief increased considerably as a direct result of the war, but the increased cost of living had made it necessary for the committee to grant larger amounts to individual beneficiaries than would otherwise have been required.

**Week-end Weather.**

The weather during the week-end appears to have been uniformly unsettled, and a member of our staff, who set out on a 180 mile road test of a new model, experienced a fair share of it. The machine was an overhead valve T.T., with chain-cum-belt transmission, and on the outward journey it proved at least 10 m.p.h. faster than the all-chain single ridden by a companion. On the return journey, through pouring rain, the chain-drive machine showed itself capable of maintaining the much higher average of the two—belt slip being, of course, the explanation. The experience served to back the old decision that belts will slip, however carefully the transmission be designed, though for fine weather riding the belt is probably preferable.

**Strikes Stop Racing in Spain.**

Cycle car and motor cycle racing on the open road is a usual thing in Spain nowadays. An important long-distance event from Barcelona to Bilbao and back was arranged for the beginning of the month, but the event had to be postponed, by order of the authorities, owing to the unrest in Spain. Strikes are, or were, prevalent in the North of Spain. There were thirty-two sporting type cycle cars among the entries—none of them British, however.

**AVERAGE PRICES.**

WE give below the prices of second-hand machines offered for sale in the last issue of *The Motor Cycle*, and in the adjoining column the average prices based upon the latest figures available. Thus the general trend of the market is visible at a glance, though in the first column many blanks inevitably occur. This is due to an insufficient number of one model on which to base an average. The word "combination" indicates a sidecar outfit as supplied complete by the makers.

Make.	Year.	H.P.	Average last week.	Previous weekly average.

A Morgan Runabout to which many clever accessories and various improvements have been added by the amateur owner. They are detailed in the accompanying notes.

## A REJUVENATED AN ENTHUSIAST'S NUMEROUS

THERE is no production of motor world which may be considered to have reached absolute finality. Makers of light cars and motorcycles often realise this, and, incidentally, profit at times from the comments or suggestions of practical riders. There are, moreover, few things which interest the rider of a particular machine more deeply than read about the improvements and additions made by a clever enthusiast of the same make. Each of the special fittings adapted to the Morgan Runabout here described is well carried out, and might almost be taken for standard work by the maker.

### Bonnet and Fan.

The machine was, originally, a standard Morgan Runabout, carrying all usual Morgan arrangements. Its date is not certain, but it is several years old, although its excellent condition leads one to suppose it to be of recent origin.

The first noticeable innovation is the bonnet. This is provided with a large number of louvres on the top and sides, and the usual space in front has a series of new-made louvre bars fitted across it. All this work is very well done and smartly finished. In lifting the bonnet a four-bladed aluminium fan stands prominently, driven by a spring belt from a pulley behind the magneto bevel driving gear. This addition has proved extremely beneficial in the matter of engine cooling. The drive absorbs practically no power.

The silencers are usually placed below the engine, but these have been removed and pipes taken to the back to separate exhaust from either side. This alteration results in a very quiet running engine; the lubricating oil tank has been arranged on the dashboard with a sight feed plunger pump, the former

*The Front of the Bonnet is fitted with Louvre Bars.*

*A Four-bladed Fan fitted to assist Engine Cooling.*

The four-bladed fan (modelled on the lines of an aeroplane propeller) is driven by a spring belt from a pulley behind the magneto driving bevel. It is found very efficient in practice.

*Showing One Silencer & Spring Gaiter!*

# MORGAN RUNABOUT.

## OWNER DRIVER'S IMPROVEMENTS.

Reservoir being taken into the petrol tank, thereby increasing the capacity. The dash has been fitted with a sliding extension carrying an adjustable screen of ample dimensions; the seat backs have been increased in height by fitting a 6in. leather band and fitting a black green leather cover to match the upholstery.

### Carrying Spares.

A large flat box mounted on a strong mild iron frame over the back mud-guard carries spare tubes, etc., while extra tool kits are formed under the seat; this gives an unusual amount of storage room for tools and kit, all easily accessible.

A neat footboard on the passenger side carries a spare petrol tin. A good point is the protection of the rear lights by enclosing them in laced-up leather gaiters. A Binks carburetter fitted. Still further, an extra large clutch and brake pedals make for eased driving comfort.

There is no need to lift the bonnet to turn the petrol on or off; a lever arrangement has been fitted to operate the petrol tap from the dash. A gate change for the gear lever in a more handy position than that originally chosen is another good feature which is well worthy of note.

These are the principal additions made by the previous owner to this fine runabout, and serve to show what scope there is for ingenuity in improving a standard model. The machine can be seen at any time at the Motor Depot, John Bright Street, Birmingham, whose courtesy we were permitted to examine it. The sketches on this and the following page show very clearly the alterations which have been so carefully carried out. It will be noted, also, by reference to the photographs, that disc wheels have been fitted throughout. Miss Hough, of the Motor Staff, speaks of this particular vehicle as the best Morgan she has handled, and her experience is by no means small.

An innovation immediately noticeable is the fitting of bars in front of bonnet, giving the appearance of louvres. The Runabout is a credit to the original owner, as it is about four years old.

The lubricating oil tank has been placed on the dashboard, and in consequence a greater capacity given to the petrol tank.

## Fan Tangent Wheel.

A NEW METHOD OF ARRANGING THE SPOKES.

Starley's patent fan tangent wheel.

**W**E have on several occasions referred to inventions by Mr. Starley, recent examples which our readers will call to mind being a tubular wheel and a front fork stamped from sheet metal. On this page we illustrate a new method of building wheels for motor cycles. Comparing this wheel with the usual tangent wheel, it is claimed that the spokes are shorter, and the wheel therefore lighter; it is quicker and easier to build; the breaking of a spoke does not affect the wheel, and it is more easily replaced—in fact, the replacement of a spoke in the usual interlaced tangent wheel is no easy matter; it is easy to clean; the belt rim can lie flat against the spokes, and the nipples exert a straight pull on the rim. A glance at the illustration shows that the lubricator in the centre of the wheel will be more than usually accessible, and that the wheel is pleasing in appearance.

The matter of appearance is, of course, not of much importance, as the spokes of a motor cycle cannot be seen when the machine is in motion, still it appeals to many persons.

## Detachable Dome Water Jacket.

Discussing a Possible Weakness in the New Scott Sociable.

**W**HEN first the writer became acquainted with the engine of the new Scott Sociable, something in its novelty of construction struck him as familiar, but in this engine, bristling with new ideas, it was difficult to locate the one part which was not exactly new. Now I have suddenly awakened to the fact that it is the ingenious and accessible manner in which the water jackets are slipped over the cylinder castings and held down thereto by the sparking plug and compression tap nipples. No amount of frost can lead to a cracked cylinder, which is a casting complete in itself, the water jacket being, as it were, merely a hood, pulled down over the cylinder casting and anchored there by the aforesaid nipples, the joint at the base consisting of a thick rubber ring.

Some years ago, before the two-stroke boom was even dreamt of in this country, I used occasionally to borrow a rowing boat—converted into a "gasolene launch"—from a neighbouring settler 'way back in a certain pioneer locality. In return for the loan of the boat I used to keep the engine in decent trim, and I recall that one minor defect which could never be cured was the leaking of water round the rubber joint which formed the point of contact between the detachable copper water jacket and the crank case casting. The water jacket of this engine, made in a pioneer city by a pioneer engineering firm, was held down in exactly the same way as the detachable water jacket of the Scott Sociable engine, but with this difference, whereas one was made of copper, the other was made of aluminium.

I believe that Mr. Scott, being an engineer of the first water, has allowed for the varying expansion of the metals used, but has he allowed for the various

whimsicalities of the thick rubber joint? And does the constant tightening up of this joint necessitate the use of a hefty hexagon spanner every time a blob of water appears adjacent to that eternal rubber joint? If so, I venture to prophesy that one will never be rid of that blob of water, and, though the leakage is negligible, it is not pleasant to look upon.

The motor boat engine referred to was designed for use in a country where keen night frosts are the common order, and I can vouch for the fact that the water contained in the jackets used, as a regular thing, to freeze solid, whereupon the engine was thawed out by pouring scalding water over the induction pipe, and starting up.

Canadian motor machine gunners aboard a Clyno machine gun sidecar. They are receiving a course of instruction at one of the M.M.G. training centres.

## ARIELS FOR THE ALLIES.

An All-green Model having Various Refinements.

A batch of  $3\frac{1}{2}$  h.p. Ariels destined for one of our Allies. A combined hand and foot clutch is fitted, also other minor alterations have been made.

YET another well known make of machine—popular alike among speedmen and the more sober-minded type of rider—to assume the garments of service green is the  $3\frac{1}{2}$  h.p. Ariel. The new model, however, departs from standard Ariel practice only in one or two minor respects, the engine and gear box remaining as hitherto, and it may be as well just to run over the detail alterations that have taken place.

It will be seen from our photographs that semi-T.T. bars of attractive design are now adopted, while the machine is, of course, finished in the green paint already familiar to our readers. Duplicate clutch control has been incorporated, the Bowden wire from the handle-bar lever having its point of attachment under the plate of the pedal, situated to the right foot of the rider, so that a double leverage is obtained for the hand clutch. It is intended that the pedal and clutch be used in conjunction, for unless the slack be taken up by the hand lever, speedy destruction of the inner wire at a point adjacent to the pedal would occur.

Dunlop heavy rubber-studded 26in.  $\times$  2 $\frac{3}{8}$ in. tyres are fitted, and the carburetter now adopted is the Amac. The gear ratios—which, though rather low for an ordinary touring model, are probably ideal for military and Overseas re-

quirements—are  $5\frac{1}{2}$ ,  $8\frac{3}{4}$ , and  $16\frac{1}{2}$  to 1. With these ratios, and with the excellent Ariel clutch to ease the engine when accelerating rapidly, very little gear changing should prove necessary.

The handle-bars of the military model are of new design, giving a comfortable riding position and excellent control

The late Ariel single-cylinder model presents several unique features which, though perhaps not entirely new to all our readers, are nevertheless worthy of passing mention while dealing with this excellent mount. The saddle is suspended on a spring pillar, which should prove an excellent substitute for a spring frame in so far as the comfort

of the rider is concerned. Starting is very much eased by the incorporation of a decompressor, operated by a bell crank pedal situated comfortably to the right heel of the rider. The design of the adjustable tappets is such that no tools are required to effect the necessary adjustment, milled discs, which engage with one another by means of a ratchet mechanism, answering the purpose of the usual lock nuts. This is a point which not only appeals to the novice—to whom the right

and the wrong way of locking the usual adjustment and of obtaining the results desired is a game of chance—but also to the experienced rider who appreciates the value of simplicity.

The Ariel gear box is another fine example of simplicity and accessibility. The necessary

### Ariels for the Allies.—

adjustments can be made in a very few seconds, and there is no likelihood of the merest novice going far wrong with these adjustments. One thing the rider should guard against, however, is to avoid too close an adjustment of the push rod, as, if the clutch plates are separated a needless distance, they are apt to over-ride the castellations. The clutch is extremely sweet in operation, and can be adjusted exactly to the requisite tension, so that it is as well to bear in mind that it is not necessary for the movement of the push rod to do more than just separate the plates.

The Ariel  $3\frac{1}{2}$  h.p. has already stood the fiery test of military usage, and from one Italian correspondent comes excellent news of the service this machine has rendered.

The point of connection between the Bowden hand control and the clutch pedal. Note also the bell crank lever for decompressor and adjustable tappet mechanism.

### PIONEER MOTORIST AS PARLIAMENTARY CANDIDATE.

THE new Conservative candidate for Central Hackney is Lt.-Commander W. G. Windham, R.N., a pioneer motorist who has had a distinguished career in many parts of the world. On the occasion of the wreck of the troopship *Warren Hastings*, Commander Windham swam ashore through a stormy sea, carrying a line by which the ropes were hauled ashore, over which some 1,200 people were drawn into safety. As a motorist he took part in the first official run from London to Brighton, and his knowledge of the industry brought about his appointment as one of the first officers of the original Army Motor Corps.

### DAMAGE IN PUBLIC GARAGES.

RIDERS are slowly realising that some risk of damage is entailed by leaving the modern machine in a public garage. For many years past our typical mount might safely be left unattended anywhere, and the worst damage which any mischievous or inquisitive person was likely to inflict was the flooding of the crank case with oil. When three-speed hubs came in they did not suffer from the attentions of those 'fidgety fools who cannot look at a machine without pulling all the levers. Nowadays the conditions are different. We have electric dynamos on many machines, kick-starters on nearly all, and usually a three-speed gear box. All these are direct invitations to the meddlesome loafer. He switches on the lamps, and if a single experiment cannot do much harm, a dozen curious visitors can easily run a battery down when the dynamo is stationary. The kick-starter suggests starting up the engine, and the next step is to try the gears. In ordinary times the staff of a

garage keeps a more or less watchful eye on the machines stored therein, but war staffs are less reliable, and we have heard of many machines put out of action whilst standing in public garages during the last month. It remains to be settled whether the machine of the future shall be designed to be meddler-proof or whether the proprietors of a garage shall be trusted to maintain an efficient watch. It is true that the garage proprietors are liable in any case, but the burden of proof is very real. For example, some loafer recently stripped the gears of one of my own machines, and it was quite impossible to prove either

(a) that the machine was perfect when I brought it in, or (b) that I had not myself stripped the gears in preparations to start next morning. ROAD RIDER.

### YOUNGER MOTOR DRIVERS.

THE desirability of temporarily lowering the minimum age for the holding of motor car driving licences has been under the consideration of the Commercial Motor Users' Association, and at the request of the Local Government Board a memorandum has been submitted. The Association suggests that the licence be issued only to a male person between the ages of sixteen and seventeen years on the written certificate of an employer that the applicant is a fit person to be licensed.

### Death of Mr. W. I. Iliffe, J.P.

WE deeply regret to have to record the death of Mr. William Iliffe, the founder and senior partner of Iliffe and Sons Ltd., the proprietors of *The Motor Cycle* and sister journals. Although for some years past he had taken no very active part in the management of the business, which owed so much to his foresight, his keen interest in it and in the modern developments of new forms of locomotion was maintained to the last.

Mr. Iliffe was of a retiring disposition, and while taking little public part in the municipal affairs of his native city (Coventry), he did a great deal of quiet unostentatious work in connection with various organisations for social betterment. His aid in this direction was not limited to mere financial assistance, but he was always prepared to give the valuable help of his full business experience and energy.

Latterly his health had been failing, but he was able to follow his usual pursuits almost uninterruptedly, dying in his sleep on the morning of July 5th at the age of 74.

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

#### SIDESLIP.

Sir,—With many machines the frame appears to get twisted, which causes the machine to fall to one side on letting go the handle-bars. This means that a slight pressure is constantly required on the handle-bars, which makes the steering bad on greasy roads, as it prevents the possibility of holding on lightly. The trick of riding over greasy roads is to hold on lightly, and the twisted frame has caused several of my sideslips.

R.E.C.

Camberley.

#### SPRINGING THE SIDECAR WHEEL.

Sir,—The article contributed by your correspondent, "Chinook," on the above subject is of special interest at the present moment, on account of the rough condition of the roads.

The springing device suggested by him is, without doubt, the best of the whole illustrations in his article. It is not, however, altogether new, as at the present moment I have one being tested which is identical, with the exception that the spring is half elliptical instead of quarter elliptical, as shown in *The Motor Cycle*. This, however, is not new, as I had one constructed some four years ago, and which was submitted to the military authorities on a gun carriage, the springing being absolutely perfect.

H. SARGINSON.

Sir,—I was much interested in the article in your issue of June 28th by "Chinook." It seems to me, however, that the old Chater-Lea arrangement was far simpler, lighter, cheaper, and just as effective as any of the devices shown. It consisted of a lever mounted on cone bearings, carrying the wheel spindle at one end and suspended by spiral springs (the tension of which was adjustable) at the other. I had this fitted to an outfit which I had built in 1904, and used it for years. It made a marked difference to the comfort, and never got out of order; moreover, I quite agree that it had the effect of relieving the stresses in the connections, which, in those days, were pretty flimsy. There is, however, another point of equal if not greater importance that should be considered by designers, and that is the question of a sidecar brake. Springing, of course, makes this more difficult, but some kind of hub brake, like the Chamberlain, should solve the problem.

D. ELYARD BROWN.

#### TECHNICAL JOURNALS FOR THE FRONT.

Sir,—It may interest you and your readers to know that there has been a splendid response to the request for technical papers for distribution amongst officers and ranks in the Motor Transport section of the Army Service Corps, Overseas.

A very large number of technical papers have been received, and parcels are being despatched on Friday of each week, and from the officer in France who has kindly taken charge of their distribution we have just heard that "The first batch of technical journals has been received and distributed to the principal M.T., A.S.C., units in France. A record is being kept of the numbers and titles of papers received, as well as to whom they have been distributed, and in view of the very large number of M.T. units in France, it would be very difficult to send too many papers."

Any further copies which your readers can spare will be most acceptable. These should be addressed to the Business Manager, *Motor Traction*, 20, Tudor Street, London, E.C.4.

We feel sure the officers and ranks of the M.T., A.S.C., Overseas will greatly appreciate any publicity which you can give to the above in your columns.

MOTOR TRACTION PUBLISHING CO., LTD.

#### WHY DOES AN ENGINE KONK?

Sir,—Permit me to congratulate your correspondent, Frank Smith, upon a remarkable mental feat. "I have not," he tells us, "seen anyone advance the theory which I hold on this subject." Consequently it is impossible for us to entertain the idea that he has even seen the article entitled "Overheating," which appeared in your issue dated April 8th, 1908—an article of which "Ixion" was good enough to remark subsequently that "every motor cyclist ought to read, learn, and digest" it.

Comparison will at once establish the fact that Mr. Smith's letter is an epitome of the median section of that article of over nine years ago, with the added illustration of the Diesel engine.

That observation of, and reflection upon, a number of familiar phenomena should lead to identical conclusions on the part of isolated observers would not call for comment. That a number of varying factors of no very obvious relationship should be equally taken into consideration under such circumstances is more remarkable. But that similar conclusions should be drawn and marshalled in the same order, with no greater essential difference than that due to form of expression, is probably little short of a minor journalistic phenomenon.

R. AYTON.

#### SPARKING PLUG DESIGN.

Sir,—"H.B." replies to my criticism on his statements *re* four-point plugs, and asserts that I doubt the fact of electrical resistance increasing with the rise in temperature, and suggests an elementary manual as a means of enlightenment.

I wish to point out to "H.B." that, being by profession an electrical engineer to a Metropolitan supply undertaking, I now have no use for elementary manuals, as electrical problems are part of my daily routine.

If he reads my previous letter correctly, he will find that I said: "Considering the high voltage, the increased resistance would be negligible."

For our worthy friend's special edification, I will give a few little simple data to prove this. The specific resistance of annealed iron at 0° C. is 9.065 per cm. cube.

Let R = resistance of metal.

A = cross sectional area in sq. cms.

B = length of metal in cms.

C = specific resistance of metal.

$$\text{Then } R = \frac{BC}{A}$$

Length of plug point, say, 4.76 mm. Cross section, 1.167 mm.

$$\text{Then } R = \frac{.476 \text{ cm.} \times 9.065}{.1167 \text{ cm.}} = 36.9746 \text{ microhms.} \\ = .0000369746 \text{ ohm.}$$

The specific resistance of pure metals increases with the rise in temperature. The formula by which one can calculate the resistance at a given temperature from its known resistance at another temperature is:

Where  $R_2$  = resistance at 100° C.

$R_1$  = resistance at 0° C.

B = difference in temperature in degrees C.

A = mean temperature coefficient 0° to 100° C.

$$R_2 = R_1 \{1 + AB\} = .00006 \text{ ohm.}$$

"H.B." has surely sufficient electrical knowledge to see now that .00006 ohm. is a negligible resistance at 8,000 volts, or 80 volts for that matter.

Even assuming the temperature of the plug points to attain treble this heat the resistance is still of no consequence.

However, the principal point of my argument, which he ignores entirely, was that the elongation of the electrode would more than counterbalance the increased resistance, a point which, by the way, I should not have raised had I doubted the variation of resistance with temperature theory.

The linear coefficient of expansion of iron per degree F. = .000007; therefore at 100° C. this would be .00126.

The expansion of plug point  $\frac{3}{16}$  in. long would = .00024 in.

From this it may be seen that the elongation question is certainly of more account than the increase of .00006 ohm, but neither is of any consequence in actual practice.

The above dimensions of plug points, etc., are only approximations, but are sufficiently accurate to prove the absurdity of "H.B.'s" statements.

Now, with reference to his remarks to the effect that the plugs whose points are "built in" from the body become hotter as the heat has further to be conducted, does "H.B." wish us to believe that the further heat travels the greater the temperature of the conductor? This, of course, is against all laws of heat and conductivity as applied to metals. It is evident that the outer electrodes, being in direct contact with the cylinder, which, by the way, is provided with cooling flanges, will require a much greater heat to raise it to the same temperature as the smaller centre electrode.

In illustration of my point, let "H.B." hold in a flame the points of an ordinary domestic pin and a large hat-pin and see which will burn his fingers first.

A. WARD.

#### PETROL FOR HOLIDAYS.

Sir,—It has just occurred to me, as manager of a munition factory which will be closing down at August time for the usual holidays of stocktaking and repairs, that there are some of our employees, both male and female, to whom a little recreation or visit to the country might be beneficial, for it would renew their energies for more work after they resume business.

Now a lot of these are owners of motor cycles. They have spent practically the whole of their capital in an article that they cannot use at the present time, and I have no doubt that there are hundreds more factories that are in the same position, namely, closing down for holidays and repairs. The workpeople will be away, and if they had a little petrol for use during this one week in August it would be a boon, and would take away a lot of the feeling that has been created against the Petrol Control Board, and members of the Government generally, on account of the restrictions that have been put on them. Cannot some of the big people in the motor cycling world approach someone in power to grant this small concession to genuine munition workers? Surely it can be done.

I am not writing this on behalf of myself, as, unfortunately, I shall have to be at the works stocktaking and on repairs. What do you think? Can anything be done for the Britisher who, although not able to go to the Front, has been just as hard at work as some of the Tommies in France?

J. LUCKETT.

[The possibility of making some such concession as outlined in the above letter has already been suggested to the Controller, and very sympathetically considered by him. He has, however, been unable to recommend that special allowances be made to the munition workers by reason of the serious petrol situation and national needs.—ED.]

#### BALL BEARING CONNECTING RODS.

Sir,—I have read with much interest the letters on this subject, and your leading article, which also refers to the same question. It does not seem to me that the two principal contestants are likely to come to an agreement, for, as you say, both writers are right from their own points of view; moreover, they are apparently reluctant to look at any other.

I do not follow "Picardy Pitt's" statement to the effect that "the crank pin centre is a point fixed outside the circle of the crankshaft, and is therefore concentric," especially when he says a few lines lower that "this piston circle, being within the circle described by the cylinders, is eccentric thereto." Again, the eccentricity does not represent "the distance the pistons reciprocate along the cylinders," but only half of this distance.

JOHN HOLLAND.

#### POST-WAR MOTOR CYCLES.

Sir,—We have had the views of the expert on post-war models, but very little support from the purely pleasure rider, who is probably the most important buyer to cater for. As a driver of motor cycles, mostly big twins, for ten years, possibly my experience may be of some little use to makers who really desire to meet the requirements of the man who uses his machine, not only for the pleasure of driving, but as a means to an end, which is, in most cases, fresh fields and pastures new.

As a matter of fact "Ixiom" has from time to time so clearly voiced our needs, that had makers only taken his suggestions as seriously as they deserved to be taken there would have been no need to put our case personally.

I write now only as a big twin driver, but whether single or twin the first consideration from the buyer's point of view is, without a doubt, price, and unless makers will be able to turn out machines at very much cheaper prices than even before the war, they had better turn their attention to other matters. I do not hesitate to assert that a very large proportion of pre-war buyers did so only by making considerable sacrifices, and it being very certain that the cost of living, rates, taxes, etc., will be considerably higher, it follows that there will be less—considerably less—money to spend on pleasure.

We shall expect to get the very best single and sidecar for £50 and the best twin outfit all on for £75. It is no use telling us that it cannot be done. Many years ago I paid £26 for a large wheel, a very small one, a piece of bent iron, and a few yards of solid rubber: to-day a far better and more complicated machine can be bought for £5 5s., and it was the American invasion that was instrumental in waking up the British maker. Let the maker beware lest history repeat itself! As regards post-war models, though the V twin will certainly take one anywhere, and there is considerable choice, I have not yet seen any V twin that was fit to sit on at any pace under 20 m.p.h., but there are times when passing over bad roads, or through lovely scenery, when you want to go your own pace, and not that of the engine's best speed. I do not look on the V twin as the be-all and end-all, but as the car evolved from one to two and from two to four and is still adding cylinders: I certainly consider that the next ideal is the four-cylinder machine. I must confess that I never heard of the Dennell before you illustrated it recently. Poor fellow! he was ten years before his time; but I think that if this machine were remodelled it would provide the best problem as a passenger machine, and I should prefer the three to the four for obvious reasons, provided that the engine were properly balanced; the cylinders should have air space between as shown; Scott's girder frame would be ideal for this engine; the seat, which should be bucket, should be a properly sprung seat, which would take the place of spring frames. Objection may be made to the three cylinders, but in practice this is quite sound. About the same period Cottereau, who was in his day an authority on car construction, built a three-cylinder car. I toured for three weeks in Scotland, with two other men and a heavy camping outfit, on this type. The car ran perfectly throughout the whole tour; the engine was well balanced, very quiet, and the fact that it was light on tyres speaks for itself; the car spent nearly every night in the open, yet never gave any trouble. I certainly think that the Dennell is worth the attention of makers, but for heaven's sake let us have twist grips, and not a lot of wretched taps to twiddle—with twist grips one can feel the very soul of the engine, with the lever one feels utterly detached. Do makers realise how many men drive American machines for this reason?

The flat twin will appeal to anyone with mechanical knowledge, but if it is going to be as complicated as it looks, and probably very expensive, it will only be within reach of the favoured few.

For my own particular fad, I sigh and sigh in vain for the 5 h.p. three-speed Scott, which would embody all the advantages of the four-cylinder without its complications.

Just a word in conclusion: spring frames, or properly insulated seats and foot-boards, for after-the-war roads, please; rigid frames should be things of the past for passenger work. I have had enough of watching my passenger's seraphic smile, whilst my spine is being reduced to pulp.

Whitefield, Lanes.

## SPARKING PLUG DESIGN.

Sir,—I have read with interest several letters about the Bosch four-point plug with the central electrode split into four ends, and also "Ixion's" remarks on it in last week's issue. I would like to add my experience of this particular plug.

A friend of mine made me a present of two of them, and I think that he must have had trouble, as when I used them they were anything but satisfactory. I tried all manner of adjustments, but at the best perfect running was only of short duration.

I decided to scrap them, but before I did so I took them to pieces, and wondered what could possibly be the advantage of four points when the spark could only use one gap at a time. So I cut three of the points off and adjusted the remaining point to .4 mm., and found, or imagined, that I had a fatter and hotter spark than ever I got from the four points. It has also proved to be so in practice, and I have never had the slightest signs of sooting up even after a twenty-five mile run, and using a quart of thin gas engine oil in this distance. I may say that my engine is a 4 h.p. Bradbury, and the gas engine oil was the only kind I could get to bring me home. The plug burned itself clean at the point, and is, like "Charley's Aunt," still running.

I think there is a lot to be said for the single-point plug, where the central electrode is one piece up to the terminal and sparking direct on to the main body of the plug.

Southport.

J. MILNER.

Sir,—On page 574 in *The Motor Cycle* of June 21st "W.F.W." attempts to reply to a previous correspondent on a type of Bosch plug. For a sensible reply I refer him to "Ixion" on the same date, who sticks to the real issue, the central electrode.

To split this portion of the plug at the point may be right or wrong, according to what happened in the process.

What is certain is that no plug with "jointed" centre-piece or earthing points is ever satisfactory. I paid 16s. for four plugs. One I threw away in disgust; one I have which sparks outside but not inside the cylinder; and one that does not spark in or out, neither on car nor cycle. The other I sold to an enemy of mine for 2s. in tin box sealed and unopened. All were guaranteed.

If "W.F.W." condemns the non-detachable insulator I am with him, as the same fault develops on English and foreign alike.

At present I am using one of the split point plugs under discussion, and I find it fires on all four points, and has done so for years. The other plug is the same brand as my 8 h.p. engine.

In both cases the central electrode is in one piece and can be removed easily, and both spark direct on the plug body. The principle is the same. No other type has been of any use to me.

J. G. BALSHAW.

## AN IDEAL MOUNT FOR A LADY.

Sir,—I must say that I do not agree with a letter which "Cadet" sent in to June 21st issue of *The Motor Cycle* re a nice lightweight for a lady munition worker, in which he states that he thinks a four-stroke would be more suitable than a two-stroke. Also I do not think that the reasons he gives are quite right. I think in many ways a two-stroke would be far more suitable for a lady rider who has not ridden a motor bicycle before than a four-stroke. The first reason that "Cadet" gives is that more miles per gallon are obtained on a four-stroke than a two-stroke. Certainly this is true to a certain extent, for the machines he mentions will do about 115 m.p.g., whereas a two-stroke in good order will do about 95 m.p.g.; but really the difference is not very much. The second reason he gives is that starting is easier on a four-stroke than on a two-stroke, but he also states that the machine should have a clutch and kick starter; with a kick starter this difficulty would be eliminated. The third reason he gives is greater speed attained by a four-stroke. Well, I have had experience with both light four-strokes and two-strokes, and think that a two-stroke when well tuned will do quite 35 to 40 m.p.h. on the level, whereas a light four-stroke will do about 45 m.p.h.; but surely a lady rider does not want to exceed 35 m.p.h. Of course, his fourth reason is a more nasty one to deal with, but, provided that good lubricating oil is used and the engine is not over-lubricated, the engine ought not to want decarbonising in less

than every 600 miles, besides any garage would do this in a few hours. Of course, there are disadvantages, such as

- (1) Cylinder more apt to get heated quickly.
- (2) Crank case always having to be kept compression-tight.
- (3) Quick formation of carbon deposit.

But I think the advantages outweigh the disadvantages, some advantages being

- (1) No valves to look after.
- (2) More evenness of torque.
- (3) Greater simplicity.
- (4) Lighter.

Also a two-stroke will climb hills better than a four-stroke of same h.p. and same gear ratio; in fact, I think more satisfaction would be got by the lady rider who had never ridden before with a two-stroke than with a four-stroke. I am, of course, saying nothing against light four-strokes, for I think they are excellent little machines.

H.C.T.P.

Abingdon.

## EXCESSIVE CHARGES.

Sir,—A short time ago I had the misfortune to smash my hub gear, and, wishing to get the repairs effected as quickly and economically as possible, I obtained from the Triumph Co. (the makers of my cycle) their spare parts list, and asked the Sturmey-Archer Gear Co. and two engineering companies who constantly advertise in your excellent paper as experts in repairs to these gears for quotations for the parts required, viz., compound cage, right-hand cage, long sliding pinion, and four right-hand pinions. The prices obtained were as follow:

	Triumph Co.	Sturmey-Archer Gear Co.	1st Engineering Company.	2nd Engineering Company.
Compound Cage ...	16/8	16/3 (12/6 + 30%)	35/-	30/-
R.H. Cage .....	6/8	6/6 (5/- + 30%)	12/6	12/6
Long Sliding Pinion	4/8	4/7 (3/6 + 30%)	7/6	8/6
4 R.H. Pinions ...	4/-	3/11 (3/- + 30%)	10/-	8/-
	£1 12 0	£1 11 3	£3 5 0	£2 19 0

If the Triumph Co. and the makers of the gear can supply at prices practically identical there is no excuse for others charging over 100% more.

Personally, I shall have nothing more to do with these two firms.

Glasgow.

DISGUSTED.

## SPARE PARTS.

Sir,—Nine months ago I procured a motor cycle and sidecar. Almost simultaneously I began reading your excellent paper. This, together with the books therein advertised, has inculcated ideas and hints which I have found invaluable indeed.

Having procured the combination, I have now endeavoured to carry out the advice as to the "spares" one should carry or have ready to hand. Among other things I have procured a valve truer, made by a well-known motor accessories company. The feeding screw has no centre point provided, and an otherwise smart little tool is blemished, *vide* the fact that it is thereby almost impossible to produce a true face. I am having a conversion made. My "bus" is made by makers world-known for the excellence of their manufactures. They have sent me on two piston rings, which have been turned to proper circle to give the necessary "spring" pressure on surface of cylinder, but it is highly evident that the "powers" that he had not enforced the need of having the rings closed and "re-turned" to suit the bore of the cylinders. The point is a most important one if proper compression is aimed at. Without this proper precaution had compression is assured, heated crank case will result, and an altogether unjustifiable condition of things be set up.

I have the greatest respect for the manner in which the internal parts of the machine have been finished, and feel positively convinced that the original rings sent with the machine must have been carefully re-turned. If so, why should the workmen be so careless when spares are under consideration? In these days of enforced economy, and when petrol is so costly, one would naturally think that makers would vie with each other in the production of perfect parts.

DAVID SHARP.

## SPORTING MORE REMINISCENCES

TROUBLES MAINLY TIRESOME. By Veteran.

BEING THE SEVENTH INSTALMENT OF THE SERIES.

Previous articles appeared in our issues of April 13th, June 15th, Sept. 14th, Dec. 21st, 1916; March 1st and May 3rd, 1917.

**T**HIS yarn is concerned with an involuntary elopement. One of my pals proposed taking his wife to Hastings for August, and as she could not drive, the puzzle was to get his motor bicycle and tricar down there. Would I drive one of them, in return for a dinner and a first-class ticket back to town? Of course I would. He put me on the tricar, with his wife in front. *En route* we lost him, and one of the front tubes came unstuck at the join. I have mended tube joints successfully at the roadside before now, but his repair outfit was of the fine old crusted order, and I made a mess of that job. 10 p.m. saw us outside a roadside inn, with the tube worse than ever. The local cycle repairer had no 26in. tubes, but he had a 28in. and we covenanted with him to reduce it to a 26in. and to post it through the inn letterbox whilst we snatched a little slumber. We came down at 5 a.m. to find that repairer did not understand that tyres are measured by the diameter, and that you must take  $2 \times 3.1416$  in. off the circumference of a 28in. tube to convert it into a 26in. As a result, he had only shortened it by 2in., and we could not tuck the superfluous 4in. of tube into the cover. By this time Esmeralda was almost in hysterics from wondering what her husband would say, and she insisted on my driving her twenty-two miles in that tricar with one front wheel tyreless. Being at that date a bachelor I did not know how to manage a tearful woman, and I did her bidding; my wrists ache to-day when I think of it. But I laughed last. When we reached Hastings we found her husband very comfortably asleep, and her rage at finding him so stoical over her possible demise was delicious to witness.

### The Tricar that Upset.

Tricars generally gave one a little tyre excitement. In the concluding stages of the tricar epoch I owned a very powerful machine which was very nearly perfect in every respect save one. If the back tyre deflated gradually, one naturally spotted what was up in time to prevent things happening. But it is literally true that if its back tyre deflated suddenly, one had precisely two alternatives, viz., either to upset in the middle of the road, or to charge the roadside. The technical reason was that the springs of the rear wheel did not permit the wheel to remain vertical when the dragging cover was squeezed over to one side or the other. With the wheel thus aslant, one could only drive the car towards that side of the road remote from the dragging cover. If one turned sharply, the tricar upset; if one let it keep nearly straight, it eventually charged the ditch, hedge, wall, or what not. In actual practice, one let oneself be guided by events; an upset was preferable to ramming a stone wall; but a soft ditch was better than a capsize on macadam. The first time I upset through trying to right the car

hastily. Three thousand miles later I took a somewhat nettlesome ditch. The third tyre burst occasioned a permanent breach between myself and a young, charming, and wealthy damozel of whom I was at the time much enamoured. It happened thuswise.

### Ker-blinkety-blunk.

Getting a brief holiday, I went to see her. Somewhere in Hampshire the back tyre burst; as there were walls about, I elected to capsize, and got up with a few immaterial cuts. I left the tricar in a barn, and trained on. When the new tyre arrived, she came down with me to fit it. The new tyre was a size too small for the rim, but I thought it might be forced on, and I laboured for an hour or two in a boiling sun, but in vain. Amaryllis had wandered away as my language warmed up, but when she had inspected the neighbourhood pretty thoroughly, she returned. "Won't it go on, darling?" I arose in my righteous wrath. "Does the blankety, blankety thing *look* as if it were blankety going on?" Amaryllis haughtily informed me she intended to marry a gentleman, and stalked off to the station with her chin in the air. Heigho! I suppose I deserved it; but motorists will sympathise with me; anyhow, it is just as well. Many parallel circumstances have arisen in my motoring experiences since then, and if she had often spoken in that tone I should certainly have murdered her. My conscience smites me much more that I sold the tricar; I ought to have burnt it, but I was a poor man. A long list of victims stands to its credit since then, but it achieved immortality when its fifth owner stuffed the rear tyre with a patent air substitute resembling grass-green sausage meat in appearance, as he said triumphantly, "It *can't* burst now!" This was true; instead of bursting it now leaks a loathsome trail of grass-green sausage meat at intervals; it takes four men of beef and brawn with crowbars to get the new tubes of green stuffing on to the rim; but, as its owner says, he bought it very cheaply, and capsizing was its one and only fault. But, between you and me, dear reader, that green stuffing is a jolly poor substitute for air, and the bumps are past belief.

### An Expensive Journey.

My worst day on record with tyres was with a car. It had six detachable wheels, and it so happened that the six covers were all nearing their dotage when need arose one blazing summer day to drive from Coventry to Bath and back within daylight. We pushed the car along very fast, and the sun expanded the air in the tubes, and the poor aged covers proved unequal to speed and heat. It sounds incredible, but we managed to burst all six covers on the double journey, and did in more than that number of tubes, seeing that we bought a new tube and dropped the old one for

## PASSENGER MOTOR CYCLES OF TEN YEARS AGO.

The instalment of "More Sporting Reminiscences" in this issue is chiefly concerning the days of the tricar. Many were the adventures in the early trials when the now defunct tricar was popular. The photograph depicts a scene during the A.C.C. (now A.C.U.) trials ten years ago. Among the makes of tricars recognisable are the Rex, Lagonda, and Riley.

repair at the next garage encountered after a tyre stop, picking up the repaired tubes on the return trip. Altogether that run cost me about £30.

A very dark night provided me with an experience and a trophy. I was picking my way homeward through the gloom in the North Country on a 5 h.p. Vindec and sidecar—no bad outfit, as things went then. But for some reason the engine refused to pull properly. Time was pressing, and it would run after a sort; the fog was getting thicker every minute, and a rapid inspection had revealed nothing amiss anywhere with the engine, carburetter, or ignition. So we reached home without effecting a diagnosis. Next morning's light showed that a lump of road metal had lodged firmly between the front tyre and the forks, thus applying a permanent brake. The curious thing about the incident was that the stone bore an exact replica of the tread of the tyre. It seemed incomprehensible that the rubber should wear the stone, until one reflected that the lump of stone was about 2in. across, and the tyre measured over 6ft. round. In other words, one may seek a parallel in an old-time machine on which the belt buffed the head off a certain protruding crank case bolt of chilled steel.

**Solid Tyres.**

I suppose that replacing solid tyres on prehistoric motor cars was probably the toughest job in the tyre line known to man. I never owned a car of the 3½ h.p. Benz persuasion, but I begged runs in one occasionally, and one of my dimmest memories is that of four men, including myself, struggling in the dark near River Hill with a solid tyre which had come off the hind wheel of a Benz Victoria. The wheel looms in my memory as if it had been 6ft. in diameter—actually I suppose it cannot have been more than 3ft. 6in. Anyhow, on numerous occasions we got about 4in. of that very tough tyre back into place, and always when the last inch looked like snicking home the other 4in. would leap gleefully off the rim and catapult its sinuous self into the darkness. I can, however, go one better than this. In those dark and

early days there was a pneumatic tyre known as the Collier, which never punctured, for the simple reason that its immense tread was made of solid rubber as thick as a brick, and much stiffer. This merit was rather compensated by the mode of attaching the tyre. Sunk in its boardlike edges were forty-eight little steel bolts, each of which had to be coaxed through a little hole in the wheel rim, after which forty-eight little nuts and forty-eight more little locknuts were applied, supposing there was any thread left on the forty-eight little bolts by the time they were forced through their forty-eight holes in the rim. Thus not only could this tyre hardly puncture, but if it did you could drive on it, for nothing short of T.N.T. would fetch it out of the rim; it took four men to get it off, even when the ninety-six nuts were removed. Well, one wet night, somewhere out on Romney Marsh, I and another man, whose very name and lineaments escape me, fitted a new 5in. Collier tyre to, I think, a big Daimler. 'Twas a weary job, readers, but when that tyre was on we knew it was all right for at least 5,000 miles.

In conclusion, may I say how I envy those bright boys who can drive a motor bicycle on the rim when all else fails? I have often tried to do so, but for one thing I cannot steer with a tyreless back wheel, and for another I cannot stick the vibration. I once got home by padding a damaged tubeless cover with straw. The latest tip under these circumstances, as published in one of America's bright and breezy journals, is to drill holes in a million whisky corks with a red hot skewer, thread the corks on copper wire, and fasten them round the rim. Next, please!

**THE NEED FOR PAPER ECONOMY.**

The only way to ensure regular receipt of this journal is to place a definite order with your newsagent or the publishers.

*This action will enable newsagents to limit their orders to the actual number of copies required, and so effect a saving of paper, labour, and railway transport.*

# THE Critic

## Fireside Chats on Motor Cycle Problems

### SAVING PETROL.

"I AM beginning to think I am an awful juggins with regard to motor cycles," frankly confessed the Novice, and, ignoring the muttered cheers of approval from the D.R., he proceeded: "Is it possible for an ordinary touring 3½ h.p. single, with the proper amount of kick behind it, to do 110 miles or thereabouts to one gallon of petrol?"

"Absolutely possible."

The Novice regarded the Journalist sceptically. "You are a competition rider, or something next door," he observed. "I am an ordinary roadfarer. What I want to know is, can the ordinary novice, like myself, obtain such results?"

"Most decidedly," stated the Journalist. "You seem to think that we fellows, to whom motor cycling is more or less of a business, are capable of exercising some superhuman influence over our machines, whereas it is merely a matter of watching the small points, which the ordinary man ignores. Small points count for everything in petrol consumption."

"Hur!" growled the Novice. "It seems to me that if you are going to get the big kick you must get the stuff through."

Here the Manufacturer became interested. "It isn't only the petrol which actually propels your machine which makes a hole in your permit," he observed. "It's the scores of petty wastages which occur on every machine unless watched. Take your carburetter—

#### Wasteful Carburetters.

"If the level is a shade too high you are apt to waste petrol wholesale, and the same applies if your needle valve requires grinding in, or if it is apt to stick. Too large a jet again affects your consumption enormously, but you must not think you can save petrol by fitting an undersize jet, which is almost, though not quite, as wasteful as an oversize."

"But let us take it that the carburetter is in proper tune," broke in the Novice, fearing one of the Manufacturer's long-winded speeches. "Mine is, I know; yet I can't do more than 80 m.p.g."

"Probably," said the Manufacturer, "you are losing petrol in a dozen ways. I suppose you flood to start?"

"Of course. Can't start without."

"Way number one! This means that you fill the whole float chamber with petrol, much of which runs to waste. It is much less wasteful to inject three or four drops through the compression Cap, or you can do it as follows. Turn on the petrol for, say, ten seconds, then turn it off again. Then rapidly depress the float by means of the 'tickle' three or four times, and the agitation in the

float chamber will cause petrol to spirt through the jet, having just the same effect as flooding. Or lean the machine over in the direction of the jet —"

"Or," stated the D.R., "if the carburetter is placed lengthwise, push the machine to the nearest 1 in 5 gradient or stand it on end against the house. My opinion is that jolly little petrol is lost in flooding unless you are stopping and starting constantly, and flooding copiously with every start. Far more fuel is lost by weak inlet valve springs, which cause blow-back through the carburetter, scattering petrol broadcast all the time you are running. That is one of the reasons why a hot-air intake generally improves one's consumption—by catching the blow-back from the air port and utilising it. Incidentally it is why a multi-cylinder engine, which maintains a constant suction on the carburetter, is more economical than a 'one-lunger.'"

"That sounds quite scientific," said the Manufacturer, "but my experience, and that of many another, points the other way and shows the single to be the most economical engine on the market, the heat losses being less in the larger cylinder."

#### Common Leakage.

"Again," put in the Journalist, "petrol is lost wholesale by filling the tank brim full—particularly in hot weather and over present-day pot-holes. Sometimes it can be seen simply spirting out of the tank ventilation, while the screw-down needles, adjusted from the top of the tank, are a common cause of leakage. The old-fashioned tap on the pipe itself is the best for economy, and you want to watch the tank fittings very carefully if after high m.p.g."

"Quite right," agreed the D.R. "I once purchased a new carburetter—a three-jet instrument, supposed to give marvellous m.p.g. Trying it, I got 60 m.p.g., which wouldn't do at all. By dint of careful adjustment, revision of jets, hot air intake, and so on, I got it up to 80 m.p.g., which I knew to be the maximum, so far as the carburetter was concerned. I then set out to discover every possible leakage by filling my tank with a half and half mixture of paraffin and petrol. My Aunt! Leaks, hitherto invisible, spirted into existence at every conceivable corner! The stopper leaked, the carburetter sprayed fuel everywhere—which was evident from the mess it made of my right trouser leg—the tank boss leaked, and at every bump a blob shot out of the tank vent."

#### Curious Facts.

The Journalist was sniffing, and evidently had something to say. "Let me tell you one or two facts about petrol consumption that may surprise you," he began. "A car is more economical for the weight it carries than a motor cycle, and a lorry more economical than a car. Why? Because a motor cycle is over-engineered, and, consequently, does not make the best of its engine. It uses its throttle lever instead of its change-speed gear. On cars and lorries we have smaller engines, running on a fixed throttle practically all the time, as it were, and using their gears on every gradient. On motor cycles everything is done by the throttle. Shall I tell you how you could beat all records on petrol consumption with a motor cycle?"

"Yes, please," said the Novice.

"Oh, do," pleaded the D.R.

"The tip's worth £50," stated the Manufacturer.

#### A £50 Tip.

"Well, just this," explained the Journalist. "Find a suitably shaped hill up which you can just manage to blind on top, with the engine pulling at its best, and the descent of which the machine will just run with gravity. On reaching the summit, stop your engine and simultaneously switch into neutral, free-wheeling down the other side."

Silence fell, broken only by the triumphant chuckles of the journalist, to whom terseness and the silencing of his fellow creatures was a real joy in life.

"Look here," broke in the D.R. at length. "We're out for the ordinary novice, and you won't save his pocket by telling him to build a road up one side of a conical hill and down the other. We have so far arrived at about ten different ways in which petrol is commonly wasted. There is one way more. Taking it that his machine is perfect in every way, a gifted rider will produce 120 m.p.g. at 33 m.p.h., where an average novice sticks at 88 m.p.g. and 23 m.p.h. Everything depends upon the rider—his judgment, his judicious handling of the controls, his art in taking corners at speed, yet without risk, and so on. The clumsy, ungifted rider will be beaten every time by the man with a natural aptitude. It is the man with the gift who tips the beam. Motor cyclists are born, not trained. So be it. Kindly pass the cigars before I get up and help myself!"

And the Journalist, knowing what it meant when the D.R. helped himself, got up promptly and politely passed the cigars.

# QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

## A Neighbourly Turn.

**?** Is it a contravention of any Act for me to present, absolutely free of charge, my neighbour with a tin of petrol?—Y.J.

No. There is no contravention of any Act in your doing this.

## Application for Renewals.

**?** I have a Douglas motor cycle, used for the distribution of newspapers. The left-hand ball bearing cup is broken, and I cannot get it mended. Can you advise me as to whether it is possible to get a certificate from the Minister of Munitions, so that I can get the Douglas people either to put in a new cup or supply me with a new wheel?—R.W.

Obtain from a post office a Munitions Form of Priority Certificate, fill it in stating what part you require, the name of the manufacturers, and the purpose for which you want the machine, and post it with a brief letter of explanation to the Ministry of Munitions, Priority Branch, 1, Caxton House, Westminster, London, S.W.1. If the Ministry sanction the order for the new part, you will be able to obtain it from the makers of your machine.

## Oil Leakage from Timing Case.

**?** My machine is a  $3\frac{1}{2}$  h.p. single, and I have experienced trouble with the oil working up the magneto drive, and then being thrown all over the gear box and my overalls. The crankshaft runs on ball bearings, and there are five holes from the crank case to timing gear. Could I fill up some of these holes? If so, what would be an easy way of doing this without taking the crank case down?—R.K.

We should recommend you to fit a fibre washer over the shaft which protrudes from the case and which drives the magneto. The washer need only be cut through one side and sprung over the shaft, being secured to the chain case by a couple of short screws. If there is room inside the case, let it revolve on the sprocket boss with its edge just inside the case, then oil which collects on it will be flung back inside the case.

Another method to prevent oil running along this shaft is to drill and tap a hole in the underside of the case, just above the bottom run of the engine chain sprocket, so that the latter still runs in an oil bath, and is not allowed to get dry. In the hole screw a short piece of pipe to lead excess oil to the ground.

## Misfiring on Hills.

**?** (1.) Can you explain the cause of my 4 h.p. 1915 Bradbury (all chain drive) misfiring on hills on high gear, and finally stopping if not changed down? This is a quite recent occurrence, as it easily climbed some of those hills on high gear a few weeks ago. (2.) What is the cause of the frequent breakage of spokes on the chain side of the back wheel of this machine? (3.) Who made the fastest lap and with what machine in the last Senior T.T. race?—T.M.C.

It is rather difficult to explain what is the cause of the misfiring on hills on high gear without a personal trial of the machine. It may be due to one of the following causes: (1.) The jet of the carburetter may be too small. Supply pipe or jet may be stopped up. Sparking plug may be faulty. Magneto contacts may require cleaning and adjusting. (2.) Frequent breakage of spokes on the chain side points to the drive being harsh, to spokes too brittle, or not of heavy enough gauge. (3.) The fastest lap in the Senior T.T. race of 1914 was made by H. O. Wood, riding a  $3\frac{3}{4}$  h.p. Scott. Time, 42m. 16s. = 53.23 m.p.h. See *The Motor Cycle*, May 28th, 1914.

## A Warped Cylinder.

**?** I have a 1915 4 h.p. Triumph, with Sturmey-Archer counter-shaft gears. On running, say, three or four miles, the crank case gets exceedingly hot, especially when running about 30-35 m.p.h., when it gets too hot to bear the hands on. I thought at first that compression was getting past the rings but have since fitted new rings. How can I increase the speed, as it is rather wanting in power when sidecar is attached, and I have to change speed for very slight hills? The compression is good.—A.V.R.

You need not be alarmed at the crank case becoming hot. Aluminium is a good conductor of heat, and absorbs a good deal from the cylinder. There is probably a slight escape of gas past the piston rings, which does not matter much, though it may indicate—as you have fitted new rings—that the cylinder is worn slightly oval. Very few engines will allow the bare hands to be placed on the crank case after running far at the speed mentioned. If you can attain a speed of thirty-five miles an hour with sidecar you are not doing at all badly. Under the circumstances we should recommend you to let well alone. Hill climbing is largely a question of good compression and moderate gear ratio.

## Fitting an Oversize Tyre.

**?** I should be glad of an answer to the following. I propose fitting a 28in.  $\times$  2 $\frac{1}{2}$ in. tyre on to the 28in.  $\times$  2 $\frac{1}{2}$ in. rim of my sidecar wheel. Is this advisable, or will it be more of a drag on the cycle? I have no doubt that it will be more comfortable for the passenger.—J.A.M.

If your rims are the standard D Section, approved by the Cycle and Motor Cycle Manufacturers' Union, you will be able to fit a 28in.  $\times$  2 $\frac{3}{4}$ in. or 28in.  $\times$  2 $\frac{1}{2}$ in. cover in place of the 28in.  $\times$  2 $\frac{1}{2}$ in. A very slight difference in the size of the tyre will make no appreciable difference in the running of the sidecar, nor will it take more power out of the engine to drive it. Where the heavier tyre scores is that it can be ridden more slackly inflated than one with a smaller section.

## Engine-shaft Clutch Adjustment.

**?** I should be obliged if you could enlighten me as to what is wrong with my 5-6 h.p. Rudge-Multi. The machine has been running fairly well until recently, when, after starting on the stand and the engine running strongly, on putting in the clutch the engine stopped dead. After repeated trials to get a start, I came to the conclusion the fault lay in the clutch, as when the engine stopped there was a kind of blow-back through the axle. I have taken out the clutch plates (which showed they had not been receiving sufficient lubrication), cleaned and well oiled them, and put the whole contrivance back, but with the same result as stated above, nor can I obtain free engine. I have some little mechanical knowledge, but I have not taken a clutch down previously. I replaced the clutch plates as follow: First, an "outer" plate and then an "inner" plate, and so on for the twenty-five pairs. I presume this is correct, and also that the plates could not be compressed "too much."—E.C.P.

Examine the lever between the clutch and the crank case by which the clutch is operated. There should be from  $\frac{1}{2}$ in. to  $\frac{3}{4}$ in. play in this lever. The holes in the axle through which oil enters to the clutch plates should be cleaned out, otherwise the clutch plates run dry. The coil springs which separate the plates for free engine position should be in good order. It is possible that through the clutch getting hot these springs have taken a permanent set, and, having lost their elasticity, they do not cause the plates to separate.

### A Lightweight Sidecar.

**?** I have a 2½ h.p. two-stroke Monopole, 1916 model, Albion two-speed, free engine, hand-controlled clutch. I wish to fix a very light sidecar, and I may say that this sidecar is only intended for a girl of eight years and not for adults. Do you think the machine is capable of this extra work?—C.M.

With a very light sidecar, and a passenger weighing not more than six or seven stone, the machine should prove capable of the work, but we do not as a rule recommend the use of a sidecar with such a low-powered machine. Still, if you keep up the engine speed by making liberal use of the low-gear, and select roads where the hills are not steep, it should give satisfactory service. Carrying a passenger on the carrier is rather different from sidecar work, as the latter presents a much larger area to wind resistance, and thus calls for increased power of propulsion.

### A Heavy Fuel Knock.

**?** I shall be glad of your advice upon the following matter. I have a 3½-4 h.p. single-gear cycle, Senspray carburetter. I have been running upon neat paraffin without any warming device of any kind. I get very good results except for one thing, and that is, a pronounced knock when starting. I start upon a carburetter full of petrol, and can continue quite well upon paraffin, but when I have occasion to stop and restart I get this bad knock, until a speed of about 8 m.p.h. is attained, when the trouble ceases, except upon stiff hills, when it will recommence in a less degree. The knock is so bad at times that I have trouble to get a start at all, and although the air is off and the spark slightly retarded, a series of back-fires occurs, as well as the knock. Tuning, etc., is correct, and on petrol only no such trouble is experienced. (1.) Will taking the petrol pipes round the cylinder tend to stop the trouble? (2.) Is there any other likely cause of such a bad knock being cured by any other adjustment? I have just cleaned deposit from the engine, ground the valves, and generally tuned the machine. When going well it seems to have more power than on petrol, but I am afraid this knocking will damage the bearings. (3.) Would magneto points being too close cause the trouble?—H.C.

We presume from your letter that the knocking has become gradually worse, in spite of the fact that you have decarbonised the engine. If this be so, and taking it that you are using the same plug, etc., it would seem to indicate that the use of the paraffin has had a detrimental effect upon the engine bearings. You make no mention of having fitted a hot-air intake, without which excessive engine wear is almost certain to accrue from the use of paraffin. (1.) It is a good plan to take the petrol pipe round the cylinder, but this does not dispense with the necessity for a hot-air intake. (2.) We would recommend you to fit a thick packing joint between the cylinder and the crank case, thereby reducing

the compression of the engine, about 3 in. should be sufficient; but you may find that the compression can advantageously be reduced further than this. Another way in which the compression can be reduced is described on page 382, column 3, of our issue of June 28th. Try also a single point plug having heavy electrodes. A lower gear ratio would probably improve matters. (3.) No, the magneto points being too close together would not cause the symptoms you describe.

### Refund for Commercial Rider.

**?** Will you give me the legal ruling on the following? I use an 8 h.p. Enfield parcel car outfit in the course of my business. I receive my allowance of petrol—twelve gallons a month, duty free. I have made application for the return of the further half tax, which is returnable on motors used for trade purposes only. Our local inspector has refused my application on the grounds that the Act states "motor cars."—S.G.W.

A motor cycle is a motor car, unless otherwise stated, within the meaning of the Act; therefore, your local inspector cannot refuse your application on these grounds.

### Decarbonisation.

**?** In a recent issue you inferred that a 3½ h.p. Sunbeam with a Sunbeam sidecar should run 2,000 to 3,000 miles without requiring decarbonising. I use good oil and handle my machine most carefully, but can never run more than 800 miles (and sidecar is usually empty) before the engine requires cleaning. I oil liberally, but not excessively. The engine gets very hot even after a few miles run. Could you recommend an oil you have tried that may give better results than I am getting?—P.T.

Your machine should certainly do more than 800 miles without decarbonising. Evidently the excess of carbon deposit is due not to imperfect lubrication, but to overheating, owing to improper carburetter adjustment. You might try a smaller jet and run always with the ignition as far advanced as possible, except, of course, when running very slowly on top. These engines generally run very coolly, and it should not be necessary to decarbonise under 1,500 or 2,000 miles.

### Economising the Petrol Supply.

**?** I am riding a 1916 A.J.S. 4½ h.p. three-speed twin. I have a small supply of petrol, which I am afraid I cannot augment, and should like your advice as to how to make my supply spin out as far as possible. The machine is perfect in every way and is only ridden solo. I use a 25 jet on carburetter, and the engine will take full air when going—no matter the position of throttle lever. (1.) Could I with advantage use a smaller jet, and if so, what number of jet would you advise (I do not want speed—25 m.p.h. and good hill climbing would satisfy me)? (2.) Could I use 25% paraffin with 75% petrol without fitting a hot-air intake?—J.J.B.

(1.) You do not mention the make of your carburetter, but we presume it is an Amac, in which case it is doubtful whether you would improve your consumption by fitting a smaller jet. A 25 jet is on the small side, but this question can only be decided by experiment on the road. (2.) We should strongly advise you to fit a hot-air intake. You would then be able to use at least 25% paraffin in perfect safety, but without such a fitment you are taking risks in using any paraffin at all. Also petrol blown back from the carburetter would be utilised. Make sure there is no leakage from the tank filler cap or elsewhere, and do not fill the tank brim full. Also avoid flooding unless absolutely necessary in order to obtain a start.

### READER'S REPLY.

#### Magneto Lighting.

With reference to the question of "A.G.M." in your issue of June 14th. He could use three 3½ volt bulbs of about 1 c.p. each, or perhaps he might possibly be able to go to 1½ c.p., but the type of lamp he talks about is the usual 4 volt 4 c.p., which utterly rules these bulbs out of the question altogether. Secondly, it will not be impossible to recharge accumulators from the magneto when we have perfected an experiment upon which we are at present working. Every magneto maker will and must say that his magneto is for ignition only, but no harm will result to any good type of magneto in using it in conjunction with the F.R.S. outfit. Where a magneto is not fitted with a cut-out terminal the makers of the lighting outfit can supply one.—F.R.S. LAMPS.

### RECOMMENDED ROUTES.

# MISCELLANEOUS ADVERTISEMENTS.

## PRICES.

**ADVERTISEMENTS** in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to **ILIFFE & SONS Ltd., and crossed** & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

## NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

## DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

## SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

## MOTOR CYCLES FOR SALE.

### Abingdon.

**A** BINGDON King Dick, late 1914 combination, 5-6 h.p., 3-speed, Gloria sidcar, excellent condition; £58.—Griffin, 89, Gt. Portland St., W.1. [4761]

**A** BINGDON, 3½ h.p., single-speed, adjustable pulley, Bosch mag., Pan seat saddle; £29/10; E.P., or exchange.—Service Co., 292, High Holborn, London. [5204]

**S**IDE CAR Outfit, 3½ h.p. Abingdon, 3-speed, splendid condition, lamps, speed indicator, perfect comfort, wind screen and hood; £45; trial after 7 p.m. by appointment; owner joined up.—Robbins, 12, Station Parade, Kew Gardens. [4855]

### A.J.S.

**A** J.S. Spares; prompt delivery.—Cyril Williams Chapel Ash Depot, Wolverhampton. [2305]

**A** J.S. Combination, 1914, 3-speed countershaft; £70; guaranteed.—Wauchope's, 9, Shoe Lane, London. [5033]

**A** J.S., 1915, 2½ h.p., 3-speed, clutch, T.T. bars, P. and H. head lamp, generator, rear lamp, tools, sound tyres, machine perfect throughout; £43/10.—Advertiser, 156, Gt. Portland St., W.1. [4205]

**A** J.S., 4 h.p., touring model, new July, 1915, not used since October, 3-speed, kick starter, handle-bar clutch, Lucas lamps, Low's patent generator, Stewart horn, tip-top condition throughout, engine runs beautifully; £60; with new Empire sidcar £74.—J. O. Philip, Sherston, Malmsbury, Wilts. [5184]

## DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

## MOTOR CYCLES FOR SALE.

### A.J.S.

**A** J.S. 1914 6h.p. Combination, in splendid condition and order; £65.—Seal and Ball, Southport. [X2147]

**A** J.S. 1916½ 6h.p. Combination, Lucas electric lighting set, electric horn, hood, hood cover, screen, speedometer, mirror, spring seat-pillar, spares, spare wheel and tyre, beautiful condition, mileage 1,800; cost £150 last September, accept £125.—24, Tenthury Rd., King's Heath, Birmingham. [X2335]

### Alldays.

**1917** Alldays Allon, shop-soiled; £40.—Jones, Garage, Broadway, Muswell Hill. [5113]

**C**OLMORE Depots, Birmingham and Manchester, for immediate delivery of Allon 2-strokes. [X0796]

**A**LLDAYS Matchless, 2½ h.p., 3-speed, 1914; £25.—H. J. Marston, 50, Argyle St., Birkenhead. [2123]

**1916** Alldays Allon, 2½ h.p., 2-speed; £35, near offer.—Broom, 77, Marylebone Lane, Oxford St., W. [4993]

**A**LLDAYS Allon, 2-speed, £35; Alldays Allon, £32/10; E.P., or exchange.—Service Co., 292, High Holborn, London. [5205]

**NEW 1917** Allons, 2½ h.p., 2-stroke models; £42; 2% only added for extended payments.—Wauchope's, 9, Shoe Lane, London. [5034]

**R**IDER TROWARD and Co., 31 and 78, High St., Hampstead.—Allon, 1916, 2-speed, 2-stroke, 29 gns.; 1915 ditto, Binks, 27 gns. [5111]

**A**LLDAYS Allon, single speed, £36; 2-speed, £42; 2-speed and hand clutch, £45; new; E.P. no extra, or exchange.—Service Co., 292, High Holborn, London. [5186]

**A**LLON 2½ h.p. 2-stroke Motor Cycle, £38/14, or on extended payments terms, deposit £7/14, and 12 monthly payments of £2/13; 2-speed and other models also supplied.—Harrods Stores, Ltd., Motor Cycle Dept., Brompton Rd., S.W. [5148]

### Ariel.

**A**RIEL, 3½ h.p., 1917, 3-speed countershaft models, in stock.—Crow Bros., Guildford. [2562]

**C**OLMORE Depots, Birmingham, Manchester, Liverpool, and Leicester, for all models of Ariels. [0797]

**A**RIEL, 3½ h.p., 2-speed, free engine, and sidcar, lamp, horn, fine condition; £23.—9, Hanbury St., E.1. [4987]

**1917** Ariels in stock; immediate deliveries; deferred payments if desired.—Jones, Garage, Broadway, Muswell Hill. [5114]

**1914** 3½ h.p. Ariel, 3-speed hub, in excellent condition; price £37/10.—Apply, J. Noble, jun., Howgate, Milton Bridge, Midlothian. [X2304]

**A**RIEL Latest 1917 3½ h.p. Combination actually in stock; £93/10.—Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green, N. [4966]

**1917** New Ariels from stock, £72; 3-speed countershaft gear, clutch, and kick start; gradual payments, 2% extra.—Wauchope's, 9, Shoe Lane, London. [5031]

### Auto-Wheels.

**A**UTO-WHEEL, 1914 model, perfect mechanical condition, good tyre; bargain, £7/10.—Advertiser, 156, Gt. Portland St., W. [5181]

**A**UTO-WHEEL, 1916 B.S.A. Model, shock absorber, excellent condition, not used 500 miles, 10 gns.; another, ordinary model, excellent condition, 8 gns.; two Raleigh cycles for same, 24in. and 26in. frames, £4/10 each.—21, Station Rd., Forest Gate, London, E. [4885]

## Loading Up the Handle-bars.

**H**ANDLE-BARS are primarily for steering, and though that significant fact is not lost sight of, very often the bars of a motor cycle are called upon to answer much the same purpose as the dashboard of a car—a space provided by nature for the mounting of numerous fitments and accessories. During the last few years we have seen one control after another transferred from the tank or elsewhere to the bars, and though the principle of full handle-bar control is to be commended, a point is reached when its advantages are all but outweighed by its disadvantages. It is known to every practical rider that the faintest drag in the steering is detrimental to the control, and though there was a period when we ourselves took a pride in the show our handle-bars presented, experience has taught us better.

Let us consider the fitments to be found on the helm of the ordinary touring mount of to-day: (1) Speedometer; (2) horn or mechanical hooter; (3) clutch control; (4) front wheel brake lever; (5) exhaust valve lifter; (6) carburetter controls; (7) magneto control and sometimes a route card—a truly formidable array, which would tip the beam at a higher point than one might imagine. Not only is the weight of all these accessories detrimental to the steering, but each—with the exception of the horn and route card—has its connecting cable, which offers a certain resistance.

Many riders object to a complication of handle-bar controls, and, besides becoming unwieldy, such a layout of goods is extremely susceptible to damage, while the handle-bars offer scant anchorage for their attachment, with the result that the accessories mounted thereupon require constant tightening. Now that we have added the clutch to the already swollen list, there is no doubt that the system requires some modification, and it would appear that the matter rests more with the makers of accessories than with the designers of machines. We

do not propose to enter here upon the advantage or otherwise of the single lever carburetter, etc. A more useful purpose might be served by urging the manufacturers of speedometers, mechanical alarms, and so forth, to design their goods so that they do not depend upon the bars for their accessibility. We are, of course, aware that speedometers driven off the rear wheel, and also many mechanical horns, are designed to be mounted on the top tube.

Certain controls must occupy the bars, and while these should be kept as simple as possible, other fitments which can just as conveniently rest elsewhere might profitably be arranged to do so.

A general reduction in handle-bar gear would be an advantage in all respects.

## Motor Cycle Mechanics—the Why and Wherefore.

**W**E commence in this issue a series of articles which will treat in a scientific manner, but without becoming too deeply technical, of some of the many problems which crop up from time to time in our columns. There are many misconceptions common among motor cyclists, which we hope these articles will do something to dissipate, and many little points which would be all the better for a little elucidation. For instance, all our readers know by this time (at least we hope so) that when turning a corner it is the inside wheel, or wheels, which tend to lift, but, if asked to explain the reason for this, many would be entirely at a loss.

This is but one of many problems in which a little scientific knowledge is desirable. We hope, therefore, that none of our readers will pass by the articles under the mistaken impression that they are dry, for we can assure them that such is not the case. They are educative as well as interesting. Further instalments will appear from time to time, though not necessarily in consecutive issues.

# IDEAS: Useful and Ingenious.

## CORKS ARE USEFUL!

**I**F a machine be fitted out with sidecar lugs which are not in use, it is a good plan to place corks in these to exclude dirt and moisture, and thus prevent rust. Similarly the open end of the saddle-pillar or any other tube can be stopped up in the same way, and for the same reason; and, moreover, a cork placed in the bottom of the head will help to preserve the front mudguard from damage if the fork springs give too much movement when passing over unusually rough roads.

Another use for bits of cork (or in this case pieces of rubber may be more suitable) is to prevent rattle between two parts which just touch or nearly do so. In all cases a little enamel to match the colour of the machine gives a neat finish.—AURIGA.

## STEERING HEAD ADJUSTMENT.

**H**AVING had a lot of trouble with the head of my machine—a 4 h.p.—working loose I got over the trouble by taking off the old nut on the fork stem and making one like the sketch. This I screwed to fit the fork

A screw clamp to prevent the steering head working loose. This takes the place of the standard nut on the fork stem.

stem, so that when once put on and tightened up by the screw in the lug on the side the threads clamp into one another. I have found this very satisfactory. I should have thought the makers would have done something of this sort to prevent the risk of the rims of the lugs holding the ball races breaking off with a very loose head.—A. E. BRADLEY, London, S.E.1.

## TO STOP DUST ENTERING STEERING COLUMN.

**A** TIP to prevent dust, etc., entering at the uncovered hole on the underside of steering column is to solder a tin disc over this hole. The solder should be run over the whole surface of the tin and the portion of crosspiece

A tip for preventing dust entering the uncovered hole underneath steering column.

which has been cleaned to prevent rust. Wear of the shackle bolt passing through the crosspiece is thus prevented. This is quite worth the trouble, and can be done in a very short time by anyone able to use a soldering iron.—DOUGLAS BARTLETT, Sec.-Lt.

## CARRYING A LEATHER CASE.

**T**HE ordinary carrier has many knobs and lugs, which play havoc with any attaché case or bag, no matter how securely attached. In the course of a run of 100 miles my leather travelling case was cut through in two places by vibra-

A felt-lined wooden carrying case for an attaché bag.

tion. A simple wooden box has been made from 3/4 in. stuff. One side is open and the whole is lined with felt. Into this the leather case slides tightly. Allowance must be made when measuring for the additional thickness of the felt. Two chamfered battens on the top side, set the length of a petrol can apart, are very useful when carrying a spare tin. The whole requires only two straps to secure tightly and does not damage the leather case. The finished article is stained dark brown. It was purposely not secured to the carrier, as it is only required occasionally; but the idea might be developed by fixing the box to the carrier with four metal straps and screws on the underside. A small hinged plate with locking arrangement could be fitted to hold the leather case in position, and straps permanently fixed to the top to hold the petrol can separately, but the simple arrangement illustrated is sufficient for ordinary purposes.—CHARCOAL (Bristol).

## RAIN ENTERING FLOAT CHAMBER.

**A**FTER a long ride in the rain one frequently experiences intermittent firing due to a drop of water settling at the bottom of the float chamber. To prevent this happening obtain an ordinary rubber ball and cut

A cover to prevent water entering the float chamber.

in half and wire over the top of the float chamber. The carburettor can still be flooded, yet the ingress of water through the "tickler" is prevented. This idea was adopted by T.T. riders to prevent the float chamber cover unscrewing with vibration; generally a piece of cycle inner tubing was used.—X.Y.Z.

### The Meddler-proof Mount.

MY own riding dates back to the days when every motor was at the mercy of any meddler, for the simple reason that we used accumulator ignition. If the engine chanced to stop with the platina in contact the accumulator automatically ran down if any loafer turned on the switch. So every manufacturer provided an owner's safety device: either the handle of the switch was detachable or else a special interrupter plug was fitted in a block at some other point of the circuit. The safety device always went into our vest pockets before we said good-night to the car or cycle. The times are just about ripe for a similar safety device in respect of lighting dynamos and gears. An interrupter plug or detachable switch key would solve the former problem, and it would not cost designers more than a few pence per mount to solve the latter. All it needs is a padlock fixing the gear lever in neutral by means of a drilled plate on the gate and a hole in the lever. Makers already realise the conditions, as they usually pack the lever in neutral with pieces of wood when they send a machine by rail. They should go further, and fit some permanent safety lock, which will always be at the owner's disposal.

### The Perfect Handle-bar.

IT is rather curious that the trade is so unanimous on the proper design of handle-bar. Look at any catalogue or any standard touring machine, and you will see a long bar, narrow across the grips, and upswept backwards. It always reminds me of a child pushing a mowing machine intended for an adult. It affords the minimum of control, induces a frightful slouch in the vertebræ, and adds nothing to comfort, since the metal is far too rigid to absorb vibration. The really workmanlike bar is of short backward reach, very wide across the grips, to give the maximum of lateral leverage in all steering imbroglios, especially for speed work and on grease, and it is fairly well dropped. How far it should be dropped depends on the rider's tastes, with a single limitation—the grips must not be so low that they can puncture the tank if the rider has a tumble. My own bars sometimes inspire the question, "Don't they make your wrists ache on a long run?" It is true that dropped grips, or even horizontal grips, take a good deal of the weight when the rider is sitting well down to his work. But I never had a wrist ache yet, save on one occasion when, reporting a trial, I rode 180 miles in the day at high speed over rough greasy roads, whereas fifty miles with the standard bar is guaranteed to give anybody a severe backache. Furthermore, the dropped grips make it easy to keep a straight back, should one wish to do, and as they throw some more of the weight on to the front wheel, they are almost an infallible preventive of the worst kind of side-slip there is—front wheel side-slip.

### The Rotaries.

HONESTLY I have played my part in winning the great war. Little did I think when years ago my frivolous chatter coaxed respectable youth by the thousand into the grimed and oil-stained army of motor cyclists that these same boys would thereby develop a mechanical bent destined to serve a war-like-purpose in Armageddon. Last week I saw a service instructor initiating a class of novices into the mystery of the Monosoupape. The instructor himself first learnt what a cam is from our pages, and the same was true of a large percentage of his pupils. But he had not imbibed our well of English undefiled. "This 'ere engine is suitable for use on either pusher or tractor machines. Wot's the difference between a pusher and a tractor, my lad? Well, when you crash on a pusher you get the crankshaft in your backbone: but with a tractor you get it in your stomach." But, bless you, they have faced death so often in hill-climbs and on the track that they don't mind that. I have just bidden goodbye to a motor cyclist-pilot of nineteen summers or so: "Good-bye, old man: look for me in the casualty list under heading 'Died of Fright.'"

### Footrests and Cornering at Speed.

THE critics who denounce spring frame machines which seem likely to foul the ground with their footrests or footboards whilst cornering at speed miss two points germane to such a discussion. The first is that since the demise of the old high frames there has hardly been a machine with which a long-legged rider would not foul his footrests in lying over round corners at speed, unless he was prepared to shunt his saddle so far back as to spoil the balance of weight. The ordinary standard wheelbase, especially in the  $3\frac{1}{2}$  h.p. class, suffers from this fault most perceptibly. A tall rider must either drop his footrests and hit the ground at moments when a jar is most dangerous, or shove his rests right forward and ride with his legs extended at a most uncomfortable angle, or put his saddle so far back that the balance is upset and carrier space trespassed upon. There is not the least reason why a sensible spring frame should be worse in this respect than existing rigid frames, few of which are perfect for riders exceeding 5ft. 9in. The second point is that the sort of rider who wants a spring frame is usually of a timid character, and does not lie over enough or take his corners fast enough to hit the ground, provided his footrest tips have a 6in. ground clearance, which is easily granted by any maker. The best solution for a tall rider is to employ foot supports which give several alternative foot positions; on standard wheelbases, especially in the  $3\frac{1}{2}$  h.p. class, it is impossible to provide him with a single satisfactory position for his feet. Only long distance riders are qualified to give verdicts on this point.

## COOLING THE ENGINE INTERNALLY.

### A Scheme to Induce all the Air for the Carburettor *via* the Crank Case. The Advantages offered by such a Scheme.

**W**HEN one comes to analyse the troubles experienced with motor cycles, few though they may be, it will be found that ninety per cent. of them are due to excessive heating of the engine. All the present talk about the use of aluminium alloys in air-cooled engine practice is with the one object of reducing to a considerable extent the working temperature of the engine, and so improving the conditions for the moving parts. Novices know that excessive heating of an engine causes knocking. Again, it rapidly results in the faces of the valves, as well as their seatings, becoming pitted to such an extent that compression escapes. Sparking plugs, too, have a much shorter life in engines developing excessive heat than in cool-running motors. Lesser known troubles, but which occur none the less, due directly to overheating, are the warping of cylinder and piston.

#### Cool the Engine Interior.

Now it has been suggested in these columns on previous occasions that the subject of internal cooling of engines has not received the attention that such an important problem warrants. If we could keep the internal parts of an engine at a comparatively low temperature, we should effect an immense saving in the consumption of lubricating oil, as it would maintain its viscosity for a much longer period, and would therefore prove a more efficient lubricant. This would be all to the benefit of the working parts. Seizing of the piston in the cylinder is a trouble occasionally experienced on the road, but particularly at Brooklands and in T.T. races, when prolonged speed bursts are the rule. This sort of thing, however, seldom occurs with a water-cooled engine, as it is much easier to maintain a film of oil between the piston and cylinder in the case of an engine running at a comparatively low temperature. How to maintain a low temperature in an engine without the complication of water-cooling is the problem which presents itself. Aluminium, as already indicated, offers immense possibilities, but there is still another promising channel which has

not been considered in detail in connection with motor cycles, and that is the desirability of drawing cool air through the crank case on its way to the carburettor. By this means—and the writer sees no great difficulties connected with the scheme—a supply of cool air could be induced into the crank case during every cycle of operations, and so assist in cooling the oil, and also the big end and other working parts of the engine. Such a system is shown in the accompanying design, the B.S.A. and Senspray type carburetters lending themselves splendidly to the arrangement under discussion. for the *whole* of the air supply could first pass through the crank case. Besides cooling the oil and the big end, many other advantages would accrue from connecting the carburettor air inlet to the crank case and providing a second air inlet on the opposite side.

#### Advantages Offered.

1. The cool rush of air is beneficial in various ways, as already mentioned.
2. The heat of the interior of the crank case would have a useful effect in warming the air on its way to the carburettor, and so assisting considerably the vaporisation of heavy spirits which are the rule nowadays.
3. A certain amount of oil fog would be drawn into the engine, which is not without its use.
4. The descending piston, during the suction stroke, acts to some extent as a pump, and assists in forcing a full charge into the engine.
5. Though the formation of carbon on the piston and cylinder head is mainly due to burnt oil, a certain amount has been proved to be foreign matter introduced *via* the carburettor. The fact that carbonaceous matter does not form on the piston and cylinder of water-cooled engines nearly so readily as on air-cooled engines indicates that we have much to make good before we approach the perfection of car engine design.

A design in which cool air is drawn through the crank case. After becoming warmed and impregnated with oil fog it is induced *via* the carburettor to the engine.

#### Objections and Means of Overcoming Them.

Now to turn to the other side of the picture. The out-

**Cooling the Engine Internally.—**

standing objection to drawing air through the crank case would be the possibility of introducing a certain amount of grit and dust, which would have a very deleterious effect upon the bearings, and might possibly score the cylinder; consequently it is imperative to design some arrangement which shall preclude all possibility of foreign matter entering the crank case. A special cylinder might be arranged with fine gauzes, though the writer is satisfied that even fine gauzes are not effectual in preventing the ingress of dust. A better system would be to draw all the air we require through water carried in a tank with a vertical baffle in the centre; this would ensure proper filtration of the air. Still another scheme suggested by the writer is shown in the smaller sketch accompanying these notes. It consists of a pipe from the crank case attached to the underside of the tank. Above is a chimney formed in the tank, and through this air is drawn *via* a dummy filler cap provided with three thicknesses of felt, or glass wool, possibly moistened.

Such a high position is purposely selected in order to get away from the dust whirls which are usually

An alternative method. In this case air on its way to the crank case is drawn through a chimney formed in the tank. Felt pads are arranged as filters in the top.

more pronounced in the region of the engine than on the top of the tank. The larger sketch, reproduced on the previous page, shows part of another idea, which is to attach a pipe of sufficient diameter to ensure an adequate air supply to the top of the petrol tank, and to draw off the petrol vapour. This moist air would give a better cooling effect than pure air, but against this one must remember the possibility of the oil being thinned and also the likelihood—though in a very distant degree—of an internal explosion due to the accumulation of gas. Again, ball valves might be necessary. The system first mentioned—to bring air through felt pads and a chimney formed in the tank—is, therefore, to be preferred.

The writer would be pleased to see comments on the idea put forward. It may be added that the type of engine shown is one having the cylinder and top half of the crank case cast in aluminium alloy in a single piece and shrunk on to a thin cast iron liner. The lower half of the crank case is, of course, of aluminium, and the possibility of readily removing it is a great advantage, as it at once exposes the big end bearing, the wear of which could be readily taken up in case of need.

G.S.

## POINTS FOR BUYERS.

### Details to Observe in Purchasing Second-hand Machines.

**A**T the present day a prospective buyer is, or ought to be, well instructed concerning the pitfalls that await people who take second-hand machines on trust. Such points as play in bearings, defective compression; and the like are dealt with in detail in the handbooks; moreover, many articles containing much useful advice have already appeared in the pages of *The Motor Cycle*. The few points I enumerate are meant to appeal to the more discerning buyer, since they are not readily brought to mind except when one's fate is to endure them.

1. Does the magneto chain receive the benefit of the oil that oozes from the main crankshaft bearings, presuming there is no more positive means of supplying it with oil?

2. Will the magneto chain case come apart without the necessity of removing such important parts as outside flywheels, clutch, and brake pedals?

3. Are the bolts that permit the magneto to slide along its supporting platform-accessible and able to be loosened with only one spanner? Magneto chains can become loose, and to lie on one's back holding the head of the bolt firm with one spanner and slackening off the nut with another is not conducive to amiability.

4. Is the gear control quadrant so arranged that the change from middle to low, and the consequent declutching, is the longest of all? One seldom changes from middle to low except when the momentum of the machine is least, *i.e.*, on hills, and it is then necessary to perform the operation as quickly as possible.

5. Are the brake and exhaust lifting levers so low in their normal position that they foul the top tube some time before the front wheel can get into the right angle position? This not uncommon defect hampers steering in no small degree.

6. Has the back brake to be removed before the rear wheel can come out?

7. Can every jolt subject one to the indignity of a stand trailing in the road?

8. Are such undesirable objects as hot exhaust pipes and unguarded plug terminals reasonably unlikely to come into contact with the rider's person?

PROGRESSIVE.

Cpl. A. Mariani, who is seen at the wheel of an 8 h.p. Morgan, was an exponent of the Indian motor cycle before joining up, and is now a Clyno instructor in the M.M.G.S.

## THREE ITALIAN MILITARY MODELS.

Italian Designers follow British Practice.

A FIRST glance at the accompanying illustrations conveys the impression that the machines shown conform to general British practice, but on examining them more closely it will be seen that the detail design is in many respects foreign to our ideas. The machines shown are made in Italy for the Italian Government, and bear the name of Stucchi. Three Stucchi models are shown—the  $3\frac{1}{2}$  h.p. single and 6-8 h.p. twin, both having chain-cum-belt drive, and a 6-8 h.p. twin, designed for sidecar use and having all-chain drive. All machines are fitted with a three-speed gear box complete with kick starter, and one of the most interesting points in their mechanism is the metal-to-metal engine shaft clutch, controlled from the handle-bars by Bowden wire, and specially designed by Signor Garelli.

Section of the Garelli gear used on the Italian Stucchi military models.

Referring to the illustration, it will be seen that the clutch consists of a simple expanding metal ring contained in the engine shaft sprocket, operated by a pair of cam-faced levers mounted on ball bearings on the engine shaft boss. The clutch would appear to be of limited diameter, though its width is ample, and it must, of course, be borne in mind that, since it runs at full engine speed, nothing like the same friction areas are

required as in the case of a geared-down clutch.

We are informed by our Italian correspondent that this clutch has been

adopted by the Italian Army, and that during trials it was found possible to effect a standing start on a sharp gradient with a  $3\frac{1}{2}$  h.p. sidecar outfit carrying three persons, and further, that the Moser people (Switzerland) have adopted this clutch for all their motor cycle engines. Our own experience of high speed, small diameter, expanding ring clutches has not been of the brightest order, however.

One apparent defect which arises from this type of clutch is the very slight reduction in gear ratio between the engine and the gear box. A large engine shaft sprocket is, of course, necessary, and therefore the chief reduction must be made between the gear box and the back wheel. This means a

small gear box pulley, high speed pinions, and reduced ground clearance for the final chain drive, owing to the necessarily large size of the belt rim.

In the sidecar machine both brakes operate on the rear wheel, one on the rim, while the other is of the internal expanding type. The chain cases appear to be good, though they lack inspection ports. The valve lifting mechanism is somewhat complicated, consisting of a long-armed bell crank lever, which actuates a smaller lever communicating with the interior of the timing case.

It will be observed that an ordinary sight drip with plunger pump is fitted for lubrication, while the control throughout is on standard lines. The tool cases are of sensible dimensions and fitted in the

An Italian made military motor cycle, the Stucchi, built specially for the Italian Army.

usual position on the carrier, though the curved carrier tube is not a very commendable feature. It will be observed also that Amac carburettors of standard type and Dixie magnetos complete what is, upon the whole, an attractive specification.

6-8 h.p. twin Stucchi, fitted with three-speed and chain-cum-belt drive.

6-8 twin designed for sidecar work, having an all-chain drive totally enclosed.

## First Instalment: SPEED AND ACCELERATION.

It is hardly necessary to point out to thinking motor cyclists the great desirability of a little mathematical knowledge—so many questions may crop up, as, for instance, the horse power required to mount a certain hill, the tension of a belt or chain when driving a heavy machine, or the calculation of a gear, that the man who is entirely ignorant of these matters must often be at a loss. In this and the following articles (of which there will be several) the author proposes to discuss some of the simpler problems dealing with speed, acceleration, force, inertia, centrifugal force, etc., and their practical application to everyday questions in a popular manner without unnecessary technicalities. No motor cyclist, therefore, need pass by these articles under the impression that they are beyond his understanding, for everything is explained in simple language.

I HAVE never been able to suppress a faint feeling of astonishment at the rapidity with which motor cyclists become versed in all the technical mysteries of their pastime (or business, as the case might be). There would be no cause for surprise if riders were recruited exclusively from the ranks of trained mechanics; but as the vast majority of them begin their initiation unhampered by any mechanical knowledge beyond that acquired, say, during the erection of a rabbit hutch for little Teddy, one cannot reasonably withhold a tribute of admiration to their adaptability. Now, while some motor cyclists have no ambition to progress very far beyond the "veriest tyro" stage, being content with the moderate degree of technical knowledge that will enable them to handle their mounts with passable skill and economy, others incline to the theoretical aspect of the sport, and become argumentative on topics such as balancing, long and short stroke engines, cam design, and so forth.

### "Miscalling Technicalities."

This disputatious class of rider is rather inclined to overlook the fact that, although an utter ignorance of Newton's laws of motion is no hindrance to becoming a highly qualified road rider, or even a T.T. winner, some acquaintance with the science of mechanics is essential to those who involve themselves in discussions of the more abstruse scientific problems connected with the motor cycle. The correspondence columns of motor cycling periodicals offer abundant proof that the proverbial little learning in these matters frequently becomes a dangerous thing. One finds such terms as work, energy, and power used as though they were practically interchangeable by writers who would be deeply offended were their ability to distinguish between a timing pinion and a carburetter float called in question. As a result of this looseness of terminology, and the unfamiliarity with elementary scientific facts of which it is the evidence, the interesting and instructive debates that arise in these columns not seldom degenerate into heated, but entirely inconclusive, interchanges of personalities.

### The Necessity of Sound Principles.

Nor is it only riders of motor cycles who would profit by an insight into the mechanical principles which underlie the operation of these machines. The average

motor cycle has not by any means shed all the objectionable unmechanical features it inherited from its humble progenitor, the bicycle; nor will it until its design is governed more strictly by the laws of mechanics. The result of the application of these rules is seen in machines such as the Scott, the Douglas, and the A.B.C., whose distinctiveness is a proof not at all of the contrariety of their designers, but of their grasp of the principles of engineering science.

If any further excuse be needed for my somewhat presumptuous attempt to make good the deficiency to which I have alluded, it is this: there are so many puzzling phenomena with which the motor cyclist is familiar that admit of no satisfactory and universally-accepted explanation—"two-stroke rattle," for instance—that there is all the more reason for leaving no ambiguity on definite points of fact which admit of no difference of opinion.

### Scientific Terms.

These articles are intended, then, for the benefit of readers who are sufficiently interested in the mechanics of motor cycling to wish to add to their knowledge of the subject, but not sufficiently so as to go to the trouble of plodding through text books. Such readers have hitherto had to rely on such scraps of information as are occasionally tendered in these columns by learned debaters who turn aside from their task of demolishing their opponents to explain some minor point in language adapted to the comprehension of the multitude. These favours, however, are usually bestowed with such an ostentatious air of condescension that the multitude can hardly be expected to relish them or to profit by them. Since no great mathematical attainments are assumed on the part of those who read the following remarks, it will not always be consistent with brevity and clearness to adhere strictly to scientific proofs and nomenclature, and I therefore think it well to ask in advance the indulgence of any keen-eyed critics who may think I have sinned in this respect. If, for example, they object to the use of "speed" and "velocity" as though they were synonymous, I beg them to believe that I am fully aware of the difference in the meaning of the terms, and to concede that no confusion can result from ignoring the distinction at times.

### Mechanics for the Motor Cyclist.—

The mechanical problems with which we shall be concerned involve primarily the measurement of distance, weight, and time. More complex quantities, such as speed, acceleration, pressure, and even volts and amperes, can be expressed in terms of these fundamental units. Thus, *speed* may be defined as rate of change of position, or distance travelled in unit time, which implies that measurements must be taken both of time and distance—a fact of which the victim of police traps is only too well aware! The speedometer relieves the rider from the necessity of actually dividing a certain number of yards or miles by a certain number of minutes or hours, but only because the calculations had already been performed during the calibration of the instrument.

Just as speed is rate of change of position, so *acceleration* is defined as rate of change of *speed*. If, at a given instant, an object has a speed of 10 feet per second, and after a lapse of three seconds its speed has increased to 25 feet per second, its *change* of speed in three seconds is 15 feet per second, and its change of speed in one second, *i.e.*, its acceleration, is  $\frac{15}{3} = 5$  feet per second. Since acceleration is  $\frac{\text{speed}}{\text{time}}$ , and speed is itself  $\frac{\text{distance}}{\text{time}}$ , we see that acceleration can be represented by  $\frac{\text{distance}}{(\text{time})^2}$ .

The most familiar example of accelerated motion is furnished by the falling of bodies under the effect of gravity. During each second of its fall a body increases its velocity to the extent of 32 feet per second, that is, its acceleration is said to be 32 feet per second *per second*. It will be seen that the popular conception of acceleration agrees exactly with the ideas here presented. If a particular make of motor cycle is credited with possessing unusual powers of acceleration, we understand that it will attain a given speed in a much shorter time after starting from rest than will some other make.

#### A Graphical Example.

It is important to observe that high speed does not necessarily imply high acceleration—an object may be travelling at a very high speed and yet have no acceleration, while it may be at rest and momentarily

have considerable acceleration. It is only *change* of speed, and not the absolute value of the speed, that determines acceleration. The accompanying diagram gives a graphical representation of the relation between acceleration and speed in the case of the motion of a motor cycle. In this diagram speed and acceleration are plotted vertically, time being plotted horizontally. Glancing first at the upper curve, we will

A graphical representation of the relation between acceleration and speed.

suppose that the point *a* corresponds to the start of a short trip. The rising portion *ab* indicates the accelerated motion with which the machine starts from rest; we may suppose that during the period of uniform speed *bc* the rider is proceeding sedately through the streets of a town; at *c* the country is reached, and the throttle is opened more generously, as shown by the rising curve *cd*. A prolonged speed burst *de* follows, until a long ascent causes the speed to fall rapidly (*ef*). The line *fg* corresponds to the climb at moderate speed up the hill, while *h* represents the point at which the equipage comes to rest, in order that the engine, the driver, and his

passenger may cool themselves in their appropriate fashions. Turning now to the acceleration curve, we see that all periods of *uniform* speed correspond with periods of *zero* acceleration. When the speed curve slopes upwards, a positive acceleration is registered, while a downward slope of the speed curve coincides with a period of negative acceleration, or deceleration.

Of course, an actual record of a motor cycle trip on these lines would not present the stiff and formal appearance of the diagram we have just considered; changes of speed and acceleration are constantly occurring, with the result that the respective curves would present a very sinuous character. It would be an easy and instructive experiment to construct at least an actual speed curve. Provided a passenger with the necessary enthusiasm could be found, all that is needed is for him to book down speedometer readings at intervals of, say, fifteen seconds. The more frequent the readings, the more interesting will the resulting curve become. It should be quite feasible to construct an instrument that would actually draw such curves—it would consist of a special type of speedometer equipped with a needle which would record the speed on a moving band of paper. One would imagine that the use of sealed recording speedometers of this kind would materially reduce the labours of observers and timekeepers during prolonged road trials.

MOHANDIS.

### WHEELS OF AGRICULTURAL MOTORS.

In view of the importance of increasing the national food supply in the present emergency, Lord Rhondda has decided to modify the Order which penalises certain agricultural motors which do not exactly comply with the regulations respecting the size of cross-

bars of their driving wheels. The new regulation is restricted to vehicles which do not exceed five tons, and also, it is to be observed, there is a justifiable clause stating that it will only have effect during the continuance of the present war.

# AN EXCELLENT HOME-MADE MACHINE.

Special Leg Shields, Electric Lights and Fittings.

SOME very interesting departures are embodied in the machine illustrated herewith. Some of these, we feel sure, will interest many of our readers with a view to adoption.

The outstanding feature about the machine is the novel way in which two tanks have been fitted at the top of the leg guards. One of these tanks is used for paraffin, or substitute, while the other one provides a watertight and very substantial compartment for tools. At first sight it would seem that these rather heavy weights at the top of the leg guards would cause the latter to rattle, but this is not the case, as we proved to our own satisfaction by a fairly long run on the machine on very third-rate roads.

## The Lighting Arrangement.

Another interesting fitting is the F.R.S. magneto lighting outfit. As we have described this recently, we have no doubt that it will be fresh in the memory of most of our readers. There is, however, one point in connection with the fitting of this particular installation that will doubtless be interesting. The rider of this machine, who is also the builder, originally fitted an ordinary single-cylinder Bosch magneto, but he found that the current generated by this was too

foot brake, which may be quite clearly seen in the illustrations.

## A Powerful Engine.

The engine is a very old design White and Poppe with a bore of 80 mm. The carburetter is of the Triumph type, but has been altered considerably to suit the owner's theories. It is of the two-lever con-

fashioned two-lever carburetter, in which one had to twiddle the air lever continuously, for the operating of this lever instantly converted the engine into the nearest approach to a  $3\frac{1}{2}$  h.p., ready for a T.T. or a timed hill-climb, that we have had the good fortune to experience

A "home made" motor cycle to which leg shields of original design are fitted. The upper part has been designed to carry paraffin as substitute on one side, and to act as a tool case on the other side.

strong for the lamps, and burnt out their filaments. Consequently, he fitted a two-cylinder Dixie magneto; but then arose a difficulty as to what to do with the current generated that should be providing a spark to a second plug. This difficulty was overcome by fitting a sparking plug into the frame near the base of the cylinder and leading the other magneto wire to it. Thus, when the machine is running, besides a spark in the cylinder, there is also a spark at the plug near the

trol type, but the air lever, instead of operating an ordinary air slide in the carburetter, operates an extra air valve placed on the engine side of the throttle valve. When we took the machine over we were carefully instructed not to open this air valve on ordinary running. However, as the machine seemed rather sluggish, we ventured to disobey instructions and to open the air valve. The result was even more remarkable than it would have been with the ordinary old-

for some time past. The engine is nearly eight years old; but, in spite of this fact, we could not help comparing it most favourably with some of the  $3\frac{1}{2}$  h.p. singles on the market at the present time, or rather, perhaps, in the middle of 1914. The pick-up of the machine proved excellent, its speed very considerable, and its hill-climbing remarkable. The speed gear fitted is a two-speed Jardine with a large clutch, both hand and foot operated.

## TEN YEARS AGO.

ALTHOUGH motor cyclists are not entirely free from criticism in these days, ten years ago the venomous hatred the sight of a motor cycle inspired in the breasts of some people was most amusing. One writer, in venting his spleen against the pastime, said that he could not conceive how an enlightened

public could suffer motor cyclists to exist at all. They resemble a portmanteau on wheels, with a hunchbacked devil crouching on the top. This hare-brained critic, being in good form, concludes a long tirade with the assertion that he had seen some people look happy in motor cars, but never by any chance had he seen people

look happy on a motor cycle. Of course, such judgment was common in those days of intolerant prejudice, when motorists were the recipients of that hatred previously given to cyclists. But a portmanteau on two wheels... and an unhappy motor cyclist! What next? Who ever saw an unhappy motor cyclist?

# THE Critic

Fireside Chats on  
Motor Cycle Problems

## AVERAGE SPEEDS.

THE D.R. stated that a friend had written to him on the subject of average speeds. This man earnestly pleaded enlightenment on the subject, saying that he had occasionally read letters in the motoring press in which writers proclaimed most extraordinary average speeds over long distances. The D.R.'s friend, though a man of some experience, had never been able to obtain such results; "and therefore," said the D.R., "I want the opinions of you chaps on the subject. What are your experiences of fair average speeds for the various powers of machines?"

The Journalist took the allusion to the press as aimed at him. "We do not hold ourselves responsible for the opinions of our readers," he quoted. "And no one knows better than we do that the ordinary motor cyclist has but the haziest notion what he is talking about when on the subject of averages."

"Gee! I should think it is!" exclaimed the Discharged Soldier. "What is the greatest distance you have done in one hour's sane riding?"

"I have done thirty-seven miles in the hour," stated the Journalist. "That was over present-day roads on a flat twin Brough. I may have done more—probably have—but I never troubled to time myself."

"And what would you average on the same machine on a journey of, say, 140 miles?" queried the Manufacturer.

"Probably 30 m.p.h. at the outside, not including drin—smokes!"

"That's about what I thought," observed the D.R. "What is your experience?" He turned to the Manufacturer.

### What High Average Means.

"I once went to Thirsk from Coventry. From Coventry to Newark the time occupied was 2h. 5m., and I proceeded from Newark to Doncaster in one hour, but that was in the very early morning. I did thirty-eight miles inside an hour. It was Creyton's machine, which had a single gear of  $4\frac{3}{4}$  to 1—a T.T. Triumph. I have travelled from Newark to Coventry (fifty-eight miles) *via* the Fosseway, during pouring rain, in 1h. 40m. All this was on open pre-war roads."

"And you were hogging it then," observed the Discharged Soldier; and next he questioned the Novice, who claimed to have done sixty miles in two hours on a  $2\frac{3}{4}$  h.p. Enfield. "I consider," he added, with visible expansion, "that *that* was my most notorious trip."

"Which goes to show that men who claim an average of 45 m.p.h. are related to Ananias!" observed the D.R.

"Or else that they are ignoring all consideration for other users of the road," added the Journalist. "If we could get rid of such bounders it would be a good thing for the pastime. My present machine is capable of 40 m.p.h. on middle and probably 60 m.p.h. on top, but under no circumstances whatever would I attempt to do forty-five miles in the hour off the track."

"Do you think you *could* do it?" queried the Manufacturer.

The Journalist pondered. "I very much doubt it, unless I could pick my road. To average thirty means keeping the needle between forty and forty-five nearly the whole of the time; to average forty-five means hovering between fifty and sixty."

"And I very much doubt it," maintained the Manufacturer. "On a T.T. Scott—probably the ablest machine on the road for high averages—I have, on deserted mountain tracks in the early morning, licked up astounding distances in the twenty minutes and half-hour, but I know what it means to cover forty-five miles in the hour."

### Sidecar Speeds.

"But let us come down to the *ordinary* rider," put in the Novice. "Take the man of the same stamp as myself, who sits his machine like a grid-iron. You chaps have a happy swing of the body which takes you safely round corners, and you never find yourself on the wrong side of the road by miscalculating your cornering abilities. What should I be able to do on, say, a good  $3\frac{1}{2}$  h.p. with sidecar and passenger?"

The general opinion was that he would be able to do about the same as he could do solo on a good baby two-stroke—about 23 m.p.h. average.

"And even that," added the Journalist, "is too fast for a lightweight. An average of 19 m.p.h. would be more judicious if you considered your engine. As for the  $3\frac{1}{2}$  h.p. sidecar, everything would depend on the road. On a level road, with no head wind, you would do your twenty-three easily, probably twenty-five. If you encountered hills or a head wind, you would drop down to nineteen ere you knew where you were."

"Talking about lightweights," interposed the Manufacturer, "I have beaten your 27 m.p.h. average of the  $3\frac{1}{2}$  h.p. single all ends up both on a  $2\frac{3}{4}$  h.p. A.J.S. and a Sunbeam of the same power."

The Journalist did not doubt it in the least, but considered that neither the Sunbeam nor the A.J.S. was a lightweight in the present order of things.

"But there were others even more remarkable," put in the Manufacturer. "The  $2\frac{3}{4}$  h.p. Humber would do 50 m.p.h.; in fact, on the track, 59 miles 670 yards have been done in the hour on one of these machines."

### The Limit.

But the Journalist pointed out that those celestial words "the track," and likewise the T.T. course, were to be left out of the discussion. "This concerns British highways," he added, "and our discussion has boiled down to the following facts: That the experienced rider, with the fastest type of machine under him—be it a high-gear V twin, a modern flat twin, or Scott two-stroke, or a T.T. single—can, if he be frivolous side out, average 37 m.p.h. at the outside. That on long journeys and on an average machine he can be well content with 27 m.p.h. That the  $3\frac{1}{2}$  h.p. with sidecar and the baby ridden solo should do 25 m.p.h., except that the baby will leave the sidecar behind against a wind or among the hills. Finally, that some of the  $2\frac{3}{4}$  h.p. singles of 1913 and 1914 were faster than some of the  $3\frac{1}{2}$  h.p. singles. Has anyone anything to add to that?"

"Yes," stated the D.R. "The average rider has an enormously exaggerated notion as to the maximum speed on the level that his machine will attain. Now I guarantee that if you took fifty  $3\frac{1}{2}$  h.p. or 4 h.p. machines, now in the hands of private owners, out of Coventry—the home of the motor cycle—not more than twenty out of the bunch would be capable of touching 45 m.p.h."

The Manufacturer and the Journalist agreed with him entirely. "At 45 m.p.h. the air begins to push one backwards off the saddle. Of course, scores of machines would do it, but the knut need not turn up his nose because the average machine will *not* do it. At 50 m.p.h. the telegraph poles are beginning to whiz past at an alarming speed. Sixty m.p.h. is dazzling, and only a born rider, with nerves of iron, can face it on an ordinary highway."

"So," summed up the D.R., "since we are, apparently, becoming famous, let us give the editor of *The Motor Cycle* something to work on. Henceforth, when the first cousin of Ananias writes him, claiming 45 m.p.h. on a Douglas, let the aforesaid editor despatch to that correspondent a printed form, on which he will find written, 'Refer to The Critics, July 19th issue.' That, I think, would put the tin hat—otherwise the trench helmet, complete with respirator—over his muzzle."

## Some B.S.A. exclusive features.

No. 4.

B.S.A. CARBURETTER.

A POINT of special interest in the B.S.A. Variable Jet Semi-Automatic Carburetter is the ease with which it lends itself to economical motor cycling. Without dismantling, the rider can alter the jet by a slight turn of the adjusting screw, and regulate the amount of petrol vaporized to suit any condition from walking pace to full power for hill climbing. The B.S.A. Carburetter is of the well-known B.S.A. quality, material and workmanship, and the B.S.A. system of perfect interchangeability is strictly adhered to.

## A DISTINCTIVE DESIGN.

The Blackburne 85 × 88 mm. Engine with Outside Flywheel and Side-by-side Valves.

The Blackburne 3 1/2 h.p. power unit. The engine is 85 mm. × 88 mm. = 499 c.c., and is one of the very few engines of that horse power possessing an outside flywheel

THE employment of the outside flywheel, though the usual practice on every type of gas, steam, and motor car engine, is seldom seen on 3 1/2 h.p. single-cylinder motor cycles. Of recent years, however, its use has become more prevalent, all the small two-strokes being so fitted, and of necessity all the flat twins. When the smooth running of any engines possessing outside flywheels is

The one-piece crankshaft as well as the connecting rod is substantially made. On the left, inlet and exhaust rockers mounted on single boss

der. The crankshaft is forged, and a split big-end used, this latter being provided with an oil scoop, which assures a plentiful supply of lubricant for this important bearing.

## Steady Turning Movement.

The engine is perhaps most remarkable for its steady pulling qualities and the manner in which it will take an unusually high gear with a minimum of gear changing. This is largely accounted for by the abnormally large flywheel, which has the further effect of transmitting a very smooth drive, and renders the engine especially suitable for sidecar use. When we speak of a large flywheel it must not necessarily be assumed that it is heavier than the usual type, for really the reverse is the case. The efficiency of a flywheel is, of course, enhanced by keeping the weight as far as possible from the centre, 20 lb. at a 3in. radius being equivalent to 10 lb. and a radius of 6in., so far as torque is concerned.

Exceedingly large bearings are utilised in this engine, and undoubtedly these bearings, together with the outside flywheel, have a good deal to do with the sweet running of the engine.

One of the illustrations shows the neat manner in which the detachable cylinder head comes away complete with valve pockets, etc. Not only is this arrangement calculated considerably to reduce the likelihood of cylinder warping, but it is an important point in the matter of accessibility. By simply removing the three top nuts the cylinder head,

The cylinder is pear-shaped, the fins being thin and cleanly cast.

Valve side of the Blackburne engine, showing cradle supports. The compact arrangement of the whole unit is commendable.

complete with valves, etc., can be lifted away so that the grinding in of the valves is relieved of ninety per cent. of its difficulties. With the cylinder head removed, the whole mechanism can be transported to the bench, where the valves can be ground in, and the carbon can be removed—these being, of course, the

The loose cylinder head and valve pockets. Note the design of the valve cap.

recommending points of the detachable combustion head. As for its possible disadvantages, present day improved methods of manufacture have removed most of these, and, given reasonable care, this point of design is practically infallible.

We understand that the makers of this interesting engine intend placing on the market as soon as possible a twin-cylinder engine having an outside flywheel and following, on general lines, the single-cylinder unit here shown.

On the occasion of the first appearance of the Blackburne motor cycle in public competition it carried off a gold medal in the A.C.U. Six Days Trials and in the London-Edinburgh M.C.C. Trial.

The details of the machine follow standard practice, a Sturmey-Archer three-speed gear box being fitted. The clutch is handle-bar-controlled, and the drive by chain and belt.

Timing pinion and cam machined from the solid.

taken into account, whether having the even torque of a flat twin or not, it is rather surprising more single cylinders do not possess them, especially those designed for sidecar work. There is a good deal to be advanced in their favour, and they are suitable for any class of motor cycle. The curious thing is the very machine which would benefit most by outside flywheels—the 3 1/2 h.p. single—usually has them inside.

## Loose Cylinder Head.

There are one or two exceptions to this rule, among them the Blackburne. This engine possesses, an exceedingly neat power unit, embodying several points of up-to-date design, with which our readers are already acquainted. In addition to the outside flywheel the engine is provided with a separate combustion head, the latter being held down by vertical rods, so designed that they provide a second point of anchorage at the base flange of the cylinder

## SPECIAL FEATURES

MECHANICS OF THE MOTOR CYCLE. COOLING THE ENGINE INTERNALLY.

## The Inspector of Petrol Consumption.

Brig.-Gen. Sir C. W. King, C.B., M.V.O., who has been appointed from a D.A. and Q.M.G. to be Inspector of Petrol Consumption, is, we understand, acting in a purely military capacity.

## Auto Cycle Union Staff on Service.

All four members of the clerical staff of the Auto-Cycle Union, of military age, joined up at the outset of hostilities, and this 100% show of patriotism has had its sad sequel in 50% casualties.

## A Lady's "Reckless" Riding.

A lady motor cyclist at Newport was recently charged at the police court with failing to stop her motor cycle when requested, and riding at a "reckless rate" with a lady on the carrier. The defendant contended that one could not do much that was daring and reckless with a 2½ n.p. machine and a passenger on the back. A fine of 8s. costs was imposed.

## The New Matchless War Model.

It was mentioned in the issue of June 14th that Messrs. Collier and Sons, Ltd., were about to place on the market a limited number of Jap-engined military model Matchless sidecar combinations, of which we gave full description, and one of the first examples of these to leave the factory is now being exhibited in the window of Messrs. Godfreys, Ltd., 208, Great Portland Street, London, W.1.

## Sports Meeting at Stamford Bridge.

Great interest is being shown by a large number of aircraft firms in the Second Annual Sports Meeting, which will be held at Stamford Bridge on Saturday, July 21st, at 3 p.m., under the auspices of the Y.M.C.A. A splendid array of prizes has been given by the leading firms for the winners of the various events which figure on the programme. Princess Iwa, of New Zealand, will sing the National Anthem and "Land of Hope and Glory," accompanied by the band of the "T" Division Metropolitan Police. H.H. Princess Helena Victoria has kindly consented to present the prizes. Admission 6d., 1s., and 2s. 6d. Further information of this event can be obtained from Mr. J. T. Clark, Sports Secretary, Y.M.C.A., Tottenham Court Road, London, W.1.

## No Motoring to Race Meetings.

The Board of Trade last week issued an Order prohibiting, with certain exceptions, the use of motor vehicles for proceeding to or from race meetings. The new restrictions say that "No person shall use or consume, or cause or permit to be used or consumed, any motor spirit for the purpose of proceeding to or from any race meeting, whether for the whole or a part only of the journey." Six clauses follow, which should very effectively achieve the end for which the

Order was designed. The Order does not apply to a public omnibus plying for hire on its ordinary route.

## Fatal Accident to Army Officer.

A motor cycle accident on July 10th resulted in the death of a gallant officer, Capt. the Hon. Edward Kay Shuttleworth. He was the only surviving son of Lord Shuttleworth, his elder brother having been killed in action in March last. He had seen much active service, and was about to return to the Front.

## MORE NEW USES FOR THE SIDECAR

A cinema operator busily filming a procession during the recent Baby Week. He has converted his A.I.S. sidecar into a temporary grandstand.

**The National War Funds.**

At the week-end the principal war relief funds stood as follow:

The National War Fund (distributed £3,641,622)	£26,213,519	0	0
The British Red Cross Fund	7,095,579	3	5
Tobacco Fund	133,475	0	0

**Motor Cyclist "Specials."**

Dozens of motor cyclists are attached to the Motor Section of the Coventry Special Constabulary, and a fine batch of men and machines were ranged up for the annual inspection on Gosford Green on July 14th.

**Petrol and Private Users.**

According to a definite statement made by the Petrol Controller within the past few days, only 10% of the petrol imported into this country is allocated to private owners, including doctors, veterinary surgeons, Government Inspectors of Munitions, Red Cross workers, and other workers of national importance.

**Sad News of a Competition Rider.**

We regret to state that W. Heaton, who competed in the last Junior T.T. Race on an A.J.S. machine, and has performed with conspicuous success in other leading competitions, passed away last week at his home near Manchester, following an attack of pneumonia. Heaton was a pioneer motor cyclist, and nearly a decade ago was a notable performer on Rex machines of that period. Latterly he turned special attention to A.J.S. motor cycles.

**Wounded Soldiers' Outing to Berkswell.**

On Saturday last many wounded soldiers from the Coventry hospitals were entertained by the Rover Co. employees. They were driven in sidecars and brakes *via* Finham Bridge, Gibbet Hill, Westwood Heath, Tile Hill, and Burton Green to Berkswell, where tea was provided at the Institute. The weather was perfect, and the outing proved most enjoyable, as well as health-giving.

**How to Advertise!**

"Wanted, 23in. Twin Triumph Motor Cycle, in good condition.—Particulars, write Box No. —."

We cull the above gem from a provincial daily paper. Possibly a domesticated would-be motor cyclist has got mixed over "Baby" and "Twin."

"Motoring.—Gentleman would like to accompany lady or gentleman for runs in country, evenings.—Box No. —."

**British Imports and Exports for June.**

The Board of Trade returns for June, compared with the previous month, show a decrease of £7,595 in the imports of motor cycle parts and tyres. Of course, no motor cycles were imported owing to the Prohibition Order.

**IMPORTS FOR JUNE.**

No. of motor cycles ..	1915..	1916.	1917.
Value of motor cycles, parts, tyres, and accessories ..	822	57	—
	£65,671	£15,192	£2,214

**BRITISH EXPORTS FOR JUNE.**

It is satisfactory to note an increase of £20,000 in the value of exports of motor cycles and parts over the May figures, and also that this year's totals are higher than the June returns of 1915 and 1916.

No. of motor cycles ..	1915.	1916.	1917.
Value of motor cycles, parts, tyres, and accessories ..	1,020	1,016	1,088
	£68,162	£71,187	£80,951

**PETROL IMPORTS.**

Number of gallons imported in June:	1915.	1916.	1917.
12,662,635 ..	19,820,337 ..	11,327,434	
The number of gallons imported during the six months of this year was:			
January ..	..	13,001,740	
February ..	..	12,257,984	
March ..	..	9,246,546	
April ..	..	10,258,951	
May ..	..	12,270,934	
June ..	..	11,327,434	

Total amount of petrol imported for the half year was 58,363,589 gallons.

**RESULT OF THE NEWCASTLE (STAFFS.) RED CROSS DRAW.**

**1st PRIZE TICKET:**  
Triumph Two-stroke } **80252**  
or £50

(Holder: A. JAKINS, Durham House  
Crouch Hill, London, N.)

**2nd PRIZE TICKET:** } **151997**  
Shetland Pony.

(Holder: H. U. DUNN, Fore Street,  
Praze, Cornwall.)

**AVERAGE PRICES.**

WE give below the prices of second-hand machines offered for sale in the last issue of *The Motor Cycle*, and in the adjoining column the average prices based upon the latest figures available. Thus the general trend of the market is visible at a glance, though in the first column many blanks inevitably occur. This is due to an insufficient number of one model on which to base an average. The word "combination" indicates a sidecar outfit as supplied by the makers, while "sidecar" implies that the fitting has been carried out by the owner.

**ROVER CO.'S EMPLOYEES' OUTING TO WOUNDED SOLDIERS.**

Sidecars and brakes ready for proceeding along the route after partaking of refreshments on Gibbet Hill, near Kenilworth (see paragraph).

## MOTOR CYCLES FOR THE FRONT.

How New and Repaired Motor Cycles  
are Distributed to the Army.

**I**N the issue of *The Motor Cycle* of June 14th we published a series of interesting photographs of derelict motor cycles saved from the war. Several readers have noticed these machines from the railway which passes the A.S.C., M.T., Depot, and many have got hold of the idea that the more hopeless ones would be sold by auction.

The object of our visit to the depot was to find out the real state of affairs, and it will be remembered that we were told that every one of these machines, except a very few which were irreparably smashed up, was overhauled by Army mechanics and was renovated.

Our next visit was to another depot, which is probably the largest of its kind in England, if not in the world. To this

place are sent all the new machines which are delivered to the Army, as well as those which pass through the repair works. The depot last visited is the distributing centre for all types. To it are sent

The crated motor cycles being taken from the goods train to the shed.

motor cycles from various corps and units for repair, and they are then sent to the chief M.T. repair depot, being returned here when they are ready to be distributed to different parts of the world.

Very shortly after our arrival we were taken by the C.O. to a railway siding at which there were being unloaded crate

**Motor Cycles for the Front.—**

after crate of Douglas and Triumph motor bicycles, which are the two favourites in the Army, and in addition to these a few other makes were to be seen in the neighbourhood, such as Rudge, Clyno, Indian, and B.S.A. It will be remembered that when motor cyclists first enlisted under the voluntary scheme in 1914 they were told to present themselves with their machines, and in a good many cases these were taken over at valuation. Many of these are still surviving, as we noticed, carefully protected by tarpaulins, such non-military makes as Scott, James, Premier, Harley-

Davidson, N.U.T., A.J.S., Humber, Thresher-Jap, Chater-Lea, New Hudson, Ariel, Bat-Jap, Bradbury, and Connaught.

Books are kept of the machines received and despatched each day, and if the figures in these books were available to the public they would make interesting reading. Very few repairs are done at this depot, the work there being to keep the various units supplied with motor cycles and cars.

The officer in charge of the motor cycles is a clergyman, who patriotically resigned his living and eventually became an officer in the A.S.C., M.T.

Where space under corrugated iron sheds is available motor cycles are stored under these, but when all the space under cover is taken up machines are left in their crates and are protected by means of tarpaulins, all bright parts being liberally smeared with grease. There are probably a couple of hundred lying in a field adjacent to the railway siding which are in a very bad

A convoy of Douglas sidecars ready to start for an A.S.C. camp.

Part of a group of broken-down motor cycles of various makes ready for repair. The tarpaulins have been specially removed to allow us to view the machines.

Unloading crated motor cycles from a railway siding adjoining the A.S.C. depot.

state of repair, and even these are covered up, as they should be to prevent further damage.

This depot covers a large area, and between the various sheds, under which all types of motor vehicles ever conceived are stored, are excellent tarred roads made of ashes from the surrounding waterworks and laid down by the A.S.C. men. Altogether the stock of motor bicycles in this particular depot exceeds 2,000.

# Military Notes

## DESPATCH RIDERS IN BAGHDAD.

OF course, motor cyclists took part in the occupation of Baghdad. No army is complete without the ubiquitous despatch rider. From Cpl. Wm. Hall, attached to the Indian Expeditionary Force, who, before the war, was a well-known member of the Ripon Motor Cycle Club, we have received the following interesting letter:

'Herewith pictures showing two D.R.'s attached to Brigade Headquarters in the historic city of Baghdad.

"The life of a D.R. out here in Mesopotamia is not an easy one. The roads are exceedingly bad, and in going across the desert one has to look out very carefully for loose sand, in which the motor cycles skid about frightfully, also deep nullahs which were formerly used for irrigating the land.

"The two D.R.'s shown (Art.-Cpl. Crichton-Smith and myself, Cpl. Hall) have been about twelve months in this country, and took part in the recent advance to Baghdad. This was a very trying time for men and machines, and a

good number of the latter suffered from overheating. Sandstorms were almost a daily occurrence, which greatly added to the discomfort of everyone. Some D.R.'s who had to leave the column with despatches had encounters with hostile Arabs, who are a source of great annoyance. More than one D.R. has lost his life by them.

"Baghdad was reached on —, and it was a very pleasant change to be able to buy a few luxuries in the numerous bazaars here thronged with people of all nationalities. There are large numbers

of motor cycles in this country, namely, Triumph, Douglas, Ariel, Rover, B.S.A., and A.J.S., and the way they stand up to the rough work is marvellous."

## FROM THE TRANSVAAL TO ENLIST.

B. C. WOODWARD, of Germiston, Transvaal, has recently arrived in England with the intention of "joining up." Mr. Woodward will be known to many South African readers, as he was a member of the firm of Ross and Woodward, motor engineers, who handled several makes of motor cycles and light cars in the Germiston district. Mr. Woodward has been a constant competitor in motor cycle events organised by the Rand Motor Cycling Club, and has competed in the Johannesburg-Durban road races, and was, indeed, the first to attempt the non-stop run with a sidecar from Johannesburg to Durban. During the rebellion in South Africa Mr. Woodward served for a short period as a despatch rider with the mounted squadron which rounded up a Muller crowd of rebels in the Eastern Transvaal. Mr. Woodward's partner, Sec.-Lt. Donald Ross, of the 4th South African Infantry, was killed in action in Delville Wood.

We have assisted Mr. Woodward, as a man of very wide motor experience, to join a technical section of the Army, and he has our very best wishes.

## 520 H.P. BIPLANES.

SOME particulars of the latest Hun raider will interest motor cyclists.

Those which raided London recently were propelled by two six-cylinder water-cooled Mercedes engines, each of 260 h.p. and a bore and stroke of 160×180 mm., with propellers aft. They are known as the Gotha type, the planes measuring 77ft. 8in. across the wings and the length being 40ft. 8in. Each carries four guns, and the normal speed is about 80 m.p.h.

Despatch riders in the ancient city of Baghdad. The mounts are a Triumph and an Ariel

Judging from the dilapidated houses in the background, the City of "Arabian Nights" received the attention of our gunners previous to the occupation.

## SERVICE ON FOUR FIGHTING FRONTS.

CONGRATULATIONS to Sec.-Lt. F. P. Mayell, who was married last Saturday to Miss Katie Bendall—his passenger always in the Indian sidecar in pre-war days.

It is many months since we heard of Mayell, who was a former official of the Sutton Coldfield A.C., the last communication coming from Egypt. Consequently, we were delighted to meet him last week during a brief leave from a most strenuous war-time existence.

Mayell has over two and a half years' Active Service to his credit, spread over four different fronts—Gallipoli, Sinai, Macedonia, and against the Senussi. Originally with the Warwickshire Yeomanry—his chum being J. H. Parsons, the Warwickshire cricketer—he took part in a bayonet charge on Hill 60 at Gallipoli, was in a cavalry charge at Quatia, and has since been four times "over the top." It was only with difficulty that we abstracted this news from our friend, who is of a naturally retiring disposition, and his chief concern when seeing us was to acquire information as to how to obtain a transfer to the "Tanks," about which he is very keen. A corporal in the Warwickshire Yeomanry, he obtained a commission last year, and is at present attached to the Worcestershire Regiment. He was disporting himself on a Baby Levis last week, though his pre-war mount was something more powerful—usually a Triumph or a twin Indian. Notwithstanding his varied experiences, Mayell looks wonderfully fit, and is possessed of the right spirit. He pointed to a scar on his forehead as the only

war scar he had to show; but we observed his service ribbon for the Boer War.

## OVER 12,000 MILITARY LETTERS.

LETTERS of application to *The Motor Cycle* on recruiting matters since war broke out have now reached a total of 12,803

□ □ □

## THE YOUNGEST DESPATCH RIDER.

ARROCHDALE reader raises the interesting question as to who is the youngest motor cyclist despatch rider to go on foreign service. The reader in question, Mr. W. Roughley, writes:

"I have wondered many times when reading *The Motor Cycle*, with occasional topics on despatch riders, if it is known who actually is the youngest D.R. to go on foreign service? My reason for the question is that my son, William Norman Roughley, who is a D.R. attached to the Royal Engineers, went out to France when he was 18 years 2 months old. I should like to hear if any of your readers can beat this. He has now been on active service nearly sixteen months."

□ □ □

## A MOTOR CYCLING COLONEL.

IT may be of interest to those motor cyclists who are serving in the A.S.C. to know that their Colonel in charge of records is an enthusiastic rider of a two-speed Baby Levis. He informs us that he wishes for nothing better, and he thinks little of getting up early in London in the summer months and riding down to some south-eastern seaside resort, breakfasting at Canterbury, then having a bathe in the sea at noon and luncheon afterwards, getting back to Town, after having tea at Maidstone, comfortably in time for dinner.

Colonel Horniblow considers that for those who wish to travel at a reasonable speed—say, twenty miles an hour—and who desire safety in all weathers, and have an eye for economy and simplicity, a two-speed two-stroke is unquestionably the machine to ride.

His advice, as an experienced horseman and polo player, is always to treat one's machine like one should a horse: study it, husband it, and care for it, and then profit and pleasure will be the result both to maker and user. Colonel Horniblow is a member of the A.C.U. and A.A., and looks forward every Thursday to *The Motor Cycle* for all the latest inventions and improvements.

Col. F. Horniblow, C.B., a keen motor cyclist.

## KILLED IN A PRACTICE FLIGHT.

WE have been informed, and learn with much regret, of the death of Fl.-Lt. Ronald Morrison, whose neck was broken through his aeroplane suddenly nose diving during a practice flight and crashing to earth. He was well-known in pre-war days at hill climbs and Six Days Trials as an amateur Douglas rider. He joined the R.N.A.S. in August, 1914, and was one of Com. Samson's four despatch riders, Cyril Pullin (invalided), Harold Plaister (invalided), and Reggie Poynting (dead) being his companions. He served in France, Belgium, and the Dardanelles.

□ □ □

## MOTOR CYCLISTS IN MESO-POTAMIA

LANCE-CORPORAL J. SUMMERS, of the 14th Light Armoured Motor Battery, writes from Mesopotamia: "*The Motor Cycle* continues to arrive regularly and is extremely welcome, as it forms our one link with civilisation, as far as motor cycles are concerned. We gather from your paper that the pastime is lying more or less dormant at present; anyway, let us hope that it will burst out with renewed vigour after the war. We are on the Tigris now, and get a show against 'Johnny' occasionally. We had quite a successful stunt a day or two ago, returning with twenty-nine prisoners, after a rather trying three hours. The cycles are sticking it as well as can be expected, especially when the bad state of the roads is considered."

## PETROL FIGURES.

NEARLY a million gallons less petrol was imported last month than in May. Yet we hear some people prophesying a bigger allowance of fuel. False prophets!

Sec.-Lt. Frank Mayell (Worcesters) and his bride Miss Katie Bendall.

# FLAT TWINS.

"IXION" REPLIES TO A CRITIC.

## Power of Exaggeration.

I MAY disarm a certain amount of criticism by drawing attention to the value of exaggeration.

It is commonly regarded with contempt or amusement. The lying angler and speedster, the enthusiast whose geese are all swans, the elderly relative who habitually adorns every tale, the journalist who works up a commonplace incident into a thrilling event—all alike indulge the same foible, consciously or unconsciously. The literally-minded moralist condemns. The excitable person with no sense of humour works himself up into an indignant passion for meticulous accuracy. The cynic coldly spirts forth his corrosive venom. The genial man of the world grins. Brown, who is accustomed to call a spade a spade, will have none of that paltering word—"exaggeration." Good old-fashioned Anglo-Saxon is his *forte*; and if a mechanic in a hurry describes half an inch as three-eighths, righteous Brown has only one word for it—the word "lie."

The value of exaggerations is twofold. First, the great British public is so confoundedly slow at the uptake that you cannot get an idea into their heads unless you isolate it, beat drums round it, turn million candle-power searchlights on it, catch as many people as you can by the scruff of the neck and rub their noses on it. Secondly, because we are constructed in this curious mould, we are provided with tutors, monitors, leaders, and prophets suffering from a huge lop-sided bias, which enables them to appreciate 99% of one aspect of a subject and practically to ignore all but 1% of the other aspect. For all which reasons it is my chiefest boast and glory that I am, under certain limitations, a naked and unashamed liar in the eyes of good old Brown and other folk of his kidney.

## An Anti-climax.

A meticulously-minded reader in the A.S.C., M.T., has been using my old comments as the Opposition in Parliament employ ancient speeches reported in Hansard against an unshakable Prime Minister. He has dug out, no doubt with commendable pains and accuracy, some weird and astounding claims of mine on behalf of the flat twin. He asserts that I said its birth had sounded the death knell of all rival types of motor cycle engine. I dare say I did. A very proper and useful thing to say. If I said it, I am proud of it. Quite untrue, of course, but most necessary. Where did the flat twin stand when war broke out? Very popular in the 350 c.c. class. Not considered or dreamt of in any other size so far as 80% of the public were concerned. Where does it stand now? Everybody is talking of "flat twins." After the war most riders who can afford to choose, and want the best, will go thoroughly into their merits. What brought the change about? Well, "Ixion's"—thank you, Brown—"lies" have had not a little

to do with it. If I was right, and the good flat twins are worthy to be set on a pinnacle alongside the vertical single and the V twin, my "lies" will have hastened its canonisation; if it is not worthy, nobody will be a penny the worse, except poor "Ixion," who will become a by-word, and may get the sack in addition. My "B.E.F." correspondent sagely opines that I shall one day eat the vow I took in these columns never to ride another vertical single. Bless you, my dear sir, if I ever made that vow, which I really forget, I ate it long ago; I am hunting at this moment for a first-rate single. Am I repentant? Not a bit of it. I feel quite normal, thank you, except that I am rather amused.

## The Faults of Flat Twins.

To show that when my "lies" have done their work I can be perfectly fair, let me quote my correspondent's catalogue of the deadly sins to which the flat twin is heir. According to him this particular type of engine is invariably prone to the following weaknesses: (1.) Abnormal cylinder and piston wear. (2.) Worn, noisy, and insecure valve mechanism. (3.) Bent crankshafts. (4.) Loosened main bearings. In his opinion these defects may chiefly be traced to excessive r.p.m. Here's a fresh bone for the dogs to quarrel over. My own opinion is reserved for the nonce.

## Evidence and Opinion.

Perhaps my foregoing confession deserves to be balanced by a statement. "B.E.F." suffers from a delusion common to many other readers of technical journals. He pictures a journalist as a needy, out-at-elbows individual, who wanders round Coventry or Portland Street begging for the loan of a machine, and who subsequently "writes up" the machine in superlatives, with an eye to the future favours of the same sort. So he speaks of my "lies" as being based on personal sampling of one type of machine, most probably a "starred demonstration" mount. I don't know who invented Grub Street, but it dies uncommon hard. Let me assure him that I am honestly quite an opulent type of individual. I had a glass of port at dinner, and I am now smoking a cigar which isn't a Flor di Fiasco. I have several machines of my very own, and I spend several hours a week in writing diplomatic letters to eager makers who want to lend me machines which I have no wish even to see. My opinions of the flat twin may be foolish, as "B.E.F." considers; or downright lies, as Brown would prefer to stigmatise them: or a judicious overstatement, planned to wake a sleepy public to the high merits of a newcomer, as I regard them. But in any case they are honest, and based on an enormous mileage distributed over many types and sizes, makes and years. The flat twin is not so new as many seem to think, *The Motor Cycle* was talking of it over ten years ago.

# SOME BIKE, SOME NIGHT, SOME MINE

By G.D.

I GOT up from my table at eleven o'clock on the evening of the 6th of June, and, throwing on a Burberry and an old gas helmet, I strolled to the cowshed garage and jerked my motor cycle from its stand. A few seconds later the engine was barking healthily, and I was jolting over the wooden track which leads from our headquarters.

It was an odd hour for motoring, and nothing but the most urgent business would have dragged me from my billet. But the attack on the lines of the enemy just south of the famous salient, though we knew it to be imminent, had come on all too quickly for my arrangements, and a forward telephone exchange, to be working by "zero," was as yet unprepared. I had despatched a lorry-load of men and appliances, and, timing my own journey, I set out to meet them in the reinforced cellar of an old French farm.

## Lights Strictly Forbidden.

A day later I might have taken my lorry there in daylight, or in darkness I could have used the most powerful of head lamps with safety. But at the time the country I traversed was in full view of the enemy on the opposite ridge, and the use of a light of any description, apart from the fact that it was strictly forbidden, would have drawn shell fire on the roads as I left them, harmless perhaps to myself, but very much the opposite to the slow-moving limbers and transport that rattled their way to the infantry in the front line trenches.

The actual roads were unknown to me, for previous visits to the farm had been made across country on foot; but a study of the map left me in no doubt of my direction. I was all unprepared, however, for the ghastly state of riding that prevailed when I had mounted the crest that was our boundary for daylight motor cycling.

As the crow flies, my destination was scarcely two miles from the ridge I have mentioned, but by road it was double the distance. The night was intensely dark, with clouds that hung heavily in the sky. Added to this there was the clatter and rumble of the vehicles that

occupied the best part of the road, and there were the pits and half-filled shell holes that abounded under their layer of dust at the edges of the *paré*.

## Riding by Shell Light.

For a while I struggled forward, my hands feeling clutch and throttle, and my foot upon the brake. For the most part I was in first gear, but at times, as star shells relieved for a moment the blackness of the surroundings, I would kick into second, and would speed up a few yards till the star shells died out and the darkness appeared to be intensified. Then I would cram on the brakes and crawl slowly forward till my eyes once more picked out the details of the track before me.

It was a night of noises that would be hard to compare. Behind me the steady reassuring rumble told of the "Heavies" that were pouring their metal and explosion to the German trenches and back areas. In front, and on all sides, were the sharp cracks of the field guns, and the comfortable "thump" of the "4.5" howitzers. Mingling with them all was the rattle of transport on cobbles, and almost unheard by comparison were the whistle and "Phil" of the gas shells that the enemy was raining on the fields around us.

## Gas Shells.

So gradually I made my way, and my trusty Triumph chugged with a steady beat, whilst the exhaust pipe glowed as if in remonstrance to the heavy treatment. And when I was little above a mile from the farm my eyes began smarting and streaming, and my nostrils proclaimed the existence of tear shells and asphyxiating gas. Then, as a star shell broke out upon the darkness, I glanced at the drivers of the transport about me, and saw that each one of them was wearing his gas helmet.

This, as you may imagine, was sufficient to frighten me to no little extent. Early in the war I had heard

"I would speed up till the star shells died down."

### Some Bike Some Night, Some Mine.—

lectures on the agonies of gas poisoning, and later I had seen men fighting for their breath, with a green foam covering their lips. And I realised with terror that the respirator I carried was not of the new and efficient type, but one of the first examples that I had owned for eighteen months and carried in accordance with the routine order.

I dragged it from its case, and hurriedly pulled it over my head. I thrust the mouthpiece between my teeth, and buttoned my tunic and Burberry tightly over the flap around my neck. And I found to my immense relief that the sickly odour of the gas had gone, and the momentary "tightness" of my lungs had disappeared.

Adjusting the goggles of the helmet, I started the engine, and set off once more over the abominable surface. The guns still cracked and rumbled, and the traffic still clattered as it jerked from stone to stone; but the thick flannel bag about my head had deadened these noises, and the beat of my own engine seemed dim and far away. Now I scarce heeded the holes through which I rode, and more than once I found myself lying in the roadway. These things seemed trivial and unnatural; I felt that I was in a dream, a figure in some way detached from myself, for ever crawling forward in a world of silent noise.

Presently I came to the farm, and drove into the yard more by instinct than intention. My men had already arrived, and were surprised at the sight I presented. I saw that they wore no respirators, and,

pulling the bag from my head, I turned to the work that was on hand.

### The Giant Mine.

The business was nearly completed when the whistle of the gas shells was heard, and the stink of the mixture detected in the cellar. Once more I donned my helmet, cursing myself again as I noticed the comparative comfort of the men in box respirators. Sweating from the heat of the night and the confinement of the cellar, we finished off wiring the exchange, and with considerable relief I jumped on my trusty motor cycle.

I had lost all count of time, and, though I did not know it, it was five minutes past three as I headed again for the highway. The lines of traffic had gone, and, save for an occasional belated limber, the roads were deserted. The guns had stopped firing, and the noise of the earlier night was replaced by a great silence.

Then, as I looked towards the east and noticed the greyness that was rising beyond the ridge, there was a burst of flame that turned darkness into a yellowish glare, and cast long vivid shadows across the roads and fields. Following upon it was a deep crashing roar and a trembling of the ground that can be likened only to an earthquake. And before I had understood it every gun and howitzer was firing at an intense rate on the German line.

It was then that I remembered the rumours of a giant mine, and realised that I had been a spectator of the greatest explosion the world has known.

"More than once I found myself lying in the roadway."

## Springing a Four-cylinder Motor Cycle.

### A Double Frame of Great Lateral Rigidity.

THE campaign in favour of spring frames inaugurated by *The Motor Cycle* has been productive of many excellent designs, suitable chiefly for single and twin-cylinder engines. The following is intended for a three or four-cylinder engine, and the designer, Mr. H. G. Pincott, of West Greenock, describes it as follows:

"The chief aim in the design of this frame is accessibility. The triangular arrangement of the tubes will make the frame very rigid. Channel frame D will support the engine as on a car, and admit of its speedy removal. The drive should be by toggle-jointed shaft and skew gear, the shaft being arranged to slide or telescope to allow springing of the back wheel. By removing the nuts A A and withdrawing

the spindles, the top part of the frame can be removed clear of the engine, and if a suitable stand be arranged to support the frame D, the whole of the engine and details will be clear for adjustment, etc. Also by

removing nut C and withdrawing the spindle, the back wheel and mudguard can be removed. The rollers E allow free movement of the laminated springs, and the tension spring B takes up backlash when bumping over pot-holes. The mudguard may be held by one or two fly nuts, and the stays pivoted on the wheel spindle inside the forks, so that by undoing the fly nuts and slacking the back spindle nuts, the mudguard can be

A spring frame primarily designed to take a four-cylinder engine.

swung out of the way for tyre repairs. The carrier can be arranged by extending rearward the two horizontal tubes under the tank."

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

#### AUTOMATIC CARBURETTERS.

Sir,—The article in *The Motor Cycle* for July 5th on one lever carburetters prompts me to ask if you, or any of your readers, can tell me the weak point of the Lukin?

I had one on a twin Rex, also on a Scott, and liked it, and got excellent mileage out of it, and would like to know why it seems to have dropped out. Was it before its time?

JAMES PEACOCK.

Leyburn, Yorks.

#### ELECTRIC HEAD LAMPS.

Sir,—On page 23 of your issue of the 5th inst. a correspondent, under the article heading of "Keeping Fit," states that he uses in his head lamp a Mazda bulb of 4 volts 1.5 amp. I should like to inform your correspondent that the British Thomson-Houston Co., Ltd., have written me to the effect that they manufacture no such bulb, the lowest size made at present being 3 amps. on 4 volts.

Possibly your correspondent uses this identical bulb, and seeing "4 v. 3 amp." thereon, with "Half-watt type," deduces that the actual consumption is one-half of 3 amps. Not so, however. I have one of the bulbs in question, and find it to give round about 20 c.p., and would point out that, owing to the extremely small size and high intrinsic brilliance of the source—the coiled filament operating in an inert gas—it is better suited for fine focus work than wide illumination, such as a motor cycle requires.

L. W. E. HARTLEY.

#### THE BELT-DRIVEN SINGLE.

Sir,—As a keen motor cyclist of over seven years' standing, with riding experience of every type of machine on the market, I should like to express the opinion, which I know to be common to many riders, that the  $3\frac{1}{2}$  h.p. direct belt-driven single will survive for many years amongst sporting riders. Personally, I prefer this type to any other on the road; it is fast, comfortable, and reliable; transmission shock is nil, consequently running cost is light; the engine, under normal conditions, turns over at a reasonable speed, without the fuss of the small twin—either flat or V.

On long journeys I prefer the  $3\frac{1}{2}$  h.p. single, as the small high-speed motor gets on one's nerves. Also, the  $3\frac{1}{2}$  h.p. is capable of maintaining the highest speed the road permits of without suffering unduly rapid wear, whereas the small machines soon knock themselves to pieces, unless the speed is kept strictly moderate.

There are several points, however, to which I should like to direct attention as easily capable of improvement.

(1.) Pistons are too heavy, usually  $1\frac{1}{2}$  lb. to  $1\frac{3}{4}$  lb. can easily be 1 lb. in cast iron, and much lighter in other materials. My own piston (steel) weighs  $12\frac{3}{4}$  oz. complete with rings and gudgeon pin.

(2.) Standard engines are, as a rule, badly balanced.

(3.) Valve gear is heavy and clumsy, and not nearly so frictionless as is desirable.

(4.) The type of roller bearing being fitted to big-ends at present is distinctly bad.

(5.) Flywheels should be external. Internal flywheels should have proper provision for being fitted dead true, both when new and when crank pins, etc., have been removed.

(6.) Crank cases should be of a better material than aluminium, and should be split horizontally instead of vertically. They should not be used as a frame member.

(7.) Cylinders and pistons should be machined throughout, both inside and out. Detachable heads are preferable.

Catford.

K.A.H.

#### THE WASTE OF PETROL IN GOVERNMENT ESTABLISHMENTS.

Sir,—With reference to the petrol shortage, one of the methods of wasting petrol has lately come to my notice. In a certain engineering works engaged on the manufacture of aero engines the following proceedings are carried out on every engine: The engine having been tested—by being run for three consecutive hours—is then dismantled, and pistons, cylinders, cranks, valves, etc., are thoroughly washed—often two or three different times—in the same grade petrol as the engines are run on, viz., the best.

I should say that to every engine turned out of these works one to two gallons of best-grade petrol is wasted in this way.

ENVOLE.

Redruth.

[We have already called attention to the great waste of petrol on several occasions. The use of gas for engine testing has been mentioned in our columns. Moreover, we have drawn the attention of officials to the question, and received the thanks of those in authority.—Ed.]

#### TWO-STROKE PISTON RINGS.

Sir,—Is it possible for you to open your columns for the purpose of ascertaining if any riders have found material benefit from the addition of Oildag to the oil?

My machine is a Junior Triumph. I weigh close on fifteen stone, yet I can run at 35 m.p.h. under favourable conditions (for, of course, short periods), but usually run round about 20 m.p.h., and have averaged just under 90 m.p.g. for the last 1,300 miles.

I, however, found it desirable to take off the cylinder every 700 to 800 miles to be reasonably sure of removing the rings without breaking them, and to remove carbon on the inlet side of piston to ensure a full charge of gas getting into the cylinder, and always found a loss of power and compression for the next 200 miles or so. If I only remove carbon from the piston and exhaust port the machine is always several miles an hour faster, but this probably means new piston rings when I eventually try to remove them.

If Oildag will keep these free for only double the time I would certainly use it, as I can easily dismantle the cylinder, clean off carbon, and replace in about twenty minutes, but when once rings are stuck one never knows what to expect.

If some of your readers, or "Ixion," have been "pioneers," perhaps they may be ready to state their experiences.

PISTON RINGS.

#### BALL BEARING CONNECTING RODS

Sir,—I believe that the question as to whether the pistons of the rotary engine are reciprocating began with a question of the inertia forces of the pistons on the crank pin in connection with the question of roller bearing connecting rods.

"Picardy Pitt" says that they are reciprocating. They are fixed to a centre and revolve. If a part fixed to a centre and revolving is a "reciprocating" part, will he kindly say what is a "revolving" part for the purpose of calculating the inertia forces? Also, will he take an example and give us the actual forces on a crank pin of an engine of the rotating type and ordinary vertical, stating what authority there is for the formula he uses in his calculations? The revolutions and weight of piston stroke can be assumed to be the same.

If any of your readers care to try for themselves the effect of the two different types they can take a ball at the end of

a piece of string. If this is whirled in a circle the string will always be tight, according to my experience. If the ball be jerked to and fro in a straight line the string will not always be tight, in my experience. This simply represents the inertia forces on the crank pin of the rotary and reciprocating engines. Anyone who cares can try this experiment, and can then form his own conclusions as to whether the use of ball bearings in the rotary type of engine necessarily means that they will be equally successful in the reciprocating.

FREDERIC STRICKLAND.

## TWO-STROKE DESIGN.

Sir,—With reference to the suggestion put forward by Mr. E. A. Rolf with regard to two-stroke design, my opinion does not quite tally with his.

First of all there would be every chance of that rod catching on the side of the tube, considering that these engines often turn at 1,500 to 2,000 r.p.m. Moreover, if we got over this difficulty the loss of compression caused by the absence of piston rings would seriously lower the efficiency of that engine. We can get over these difficulties by slightly altering the cylinder design, as shown by accompanying sketch.

But even this would not get over the other difficulties, which would render the engine totally inefficient; these are the increase in weight of the piston, the supplementary friction caused by the rod, and the greater friction caused by the need of a bigger bore to keep up the capacity of engine.

JEAN CALLEBAUT.

The piston is at the bottom of the stroke; the rod, although being still held by cylinder, uncovers holes A and B, through which the mixture rushes.

## SHOCK ABSORBERS.

Sir,—I thank "Chinook" for his reply on the above subject, and I can assure him that I had not overlooked the facts he mentions with regard to the uneven torque at low top-gear speeds.

The hammer and nail analogy I prefer to ignore, since such things are like poison gas, in that they often become as dangerous to the user as to the opponent, and consequently I will confine myself to the actual mechanical problem in hand.

According to my contention, "Chinook" reasons that the final belt drive must be so tensioned that the shock absorbing qualities are lost when running on top gear. I ask if this is not indeed true, in so far as those qualities are dependent upon tension: for undoubtedly the indirect belt is distinctly harsher than the direct, simply because surface slip between belt and pulley is practically eliminated by the increase of frictional contact between them and by the excessive tightness necessitated by the short belt centres.

Such shock absorbing qualities as now remain lie in the elasticity of the material, and also in the fact that at low top gear speeds, when the torque is noticeably uneven, the inertia effect of the whole machine moving through space will tend to cause it momentarily to overrun the engine between each power stroke, with the result that there will be periodically recurring incidents when the belt will be fed over the countershaft pulley, thus allowing slip proportionate to the unevenness of the torque.

If "Chinook" has ever ridden machines fitted with N.S.U. or Millennium engine shaft gears he will need no further proof of the necessity of excessive tension to counteract the slip induced in a geared-down belt transmission.

The above mentioned shock absorbing powers in a final belt drive will be non-existent in the low-speed device suggested. Moreover, the large amount of frictional area and spring pressure would form such an obstacle to compactness of design that it is scarcely conceivable that it could be added to rear sprockets already cluttered up with internal brakes, detachable wheels, and chain cases. Again, if steel and bronze plates were used, provision would have to be made for constant lubrication and the exclusion of grit—no mean difficulty when one recollects the interior condition of

many "totally enclosed" coil spring "cush" sprockets, whilst the dry plate (Ferodo) type, necessarily bulky even as a high-speed clutch, would become a monstrosity in this position.

In conclusion, I must thank "Chinook" for the pleasant chain of associative memories aroused by his mention of Park Rash. May we all have the good fortune to be able to resume our hill-hunting expeditions in the near future.

WHARFEDALE, A.S.C.,—M.T.

## KONKING ON HILLS.

Sir,—I should be greatly obliged if any of your readers could account for the following phenomenon which occurs with a well-known long-stroke single-cylinder motor cycle engine. It has puzzled me for a considerable period, and I confess I am beaten.

When I start from cold, the acceleration is terrific—the engine will roar away in fine style—with no suspicion of a konk or a knock. But if I have been running for a short time—say ten minutes—and I stop for a minute and then start again, while the engine is picking up a series of tremendous konks occurs, as though the cylinder were being hit by a hammer.

Now I have often been prevented from climbing a stiff hill owing to this wretched konk. If I can manage to rush the hill I shall get up all right, but if I slow down whilst climbing I cannot manage to get up at all; but if I stop halfway up the hill, and allow the engine to get absolutely cold, I shall roar up the hill without the slightest difficulty.

I have noticed that when these konks occur a cloud of bluish smoke always comes out of the exhaust pipe, following the stroke of the piston; this would look like a mixture knock, but I do not think it is. The valve timing is absolutely correct; I have checked it several times. The ignition is timed correctly. Mixture right. I have tried bigger jets, smaller jets, extra air, etc. There are no air leaks. The cylinder never gets at all hot. I am certain the plug points do not get incandescent, and there is no doubt that it is not a carbon particle.

Can any of your readers tell me why this is? The engine, by the way, is 100×79.

H. W. WILLIAMSON (Lt. M.G.C.).

## AN IDEAL MOUNT FOR A LADY.

Sir,—As a rider—civil and military—of some ten years' experience, I should like strongly to back up your correspondent, "H.C.T.P.," in advocating the two-stroke as having every advantage for a non-mechanical rider, lady or gentleman. My mount has been on the road for three years without a single mechanical stop of any kind. My wife had about ten minutes' instruction on it and then at once successfully completed a forty-mile journey—she had never had anything to do with any kind of motor previous to that occasion.

The three disadvantages put forward by your correspondent do not bear much weight with a properly lubricated mount. (1.) "Cylinder more apt to get heated quickly" is a comparative statement of no value; it need not, and mine does not, ever overheat if driven reasonably.

(2.) "Crank case always having to be kept compression-tight" is an absolute fallacy. Astounding as it may appear, I can vouch for the fact that mine was once driven a whole day by a friend with the crank case drain tap fully open through an oversight. The only fault he found on returning it was that it did not seem to take so much air; when I pointed it out to him, he declared that there was practically no difference in the running or power from the time he had previously borrowed it.

The most extraordinary experience I had was when finding the platinum points almost gone I tried to fix two new points which I had by me. After about 100 miles the engine began to misfire occasionally; examination proved that one point had dropped off, and thus the other did not meet the arm, from which it had dropped by about  $\frac{1}{16}$  in. It still fired fairly regularly and took me home all right. Can any of your readers explain either of these last two experiences? Finally, if lubricated properly—not petrol—decarbonisation is not necessary under 800 to 900 miles, and can be easily made a good job of in an hour. I am certain that a good modern two-stroke is the most reliable and fool-proof motor cycle made.

ROYLAT.

Ipswich.

**A BOARD OF TRADE ANNOUNCEMENT.**

Sir,—I notice in your issue of *The Motor Cycle* of June 28th, under the heading of "Current Chat," a paragraph headed "A Board of Trade Announcement," in which is stated, "The Board of Trade is compiling a directory of *British and Irish manufacturers*." Surely Ireland is British? Do not the British Isles comprise Great Britain and Ireland? I would not mind if you had put "British and South Irish." Pembroke.

A BELFAST MAN.

[Our correspondent, with whose views we sympathise, must not blame us, but the Board of Trade. We used the words contained in its announcement.—Ed.]

**SPARKING PLUG DESIGN.**

Sir,—May I encroach upon your valuable space in reply to "H.B.," re the "Four-point Plug," which, although a good plug in other respects, soots up rapidly? As anyone with quite an elementary knowledge of the multiplication table would admit,  $4 \times 1$  cannot by any mathematical jugglery resolve itself into anything but 4. With regard to your correspondent's electrical theories, I should advise him to attend an elementary class in "electricity" before rushing into print with such obvious errors, as I am afraid that the manual referred to by him in your issue of June 21st is considerably out of his depth. Granted his contention about increase of resistance, did he ever contemplate that, although another drop in an ocean makes it larger, the proportion would turn his hair grey if he attempted to work it out? The "elongation" suggestion by Mr. A. Ward certainly more than counteracts the increase of resistance; but, after all, what "splitting of hairs." R. C. FORDHAM.

Instructor of Electrical Engineering L.C.C.

**ALUMINIUM CYLINDERS.**

Sir,—I notice your evident enthusiasm for aluminium as a cooling medium when applied to the cylinder of an internal combustion engine either in the form of a jacket or cast upon the iron cylinder.

The heat conductivity of aluminium is not disputed for an instant. The conductivity of aluminium in this respect is second only to copper, which has the highest heat (and consequently electrical) conductivity known. I have carefully read all your articles on the subject, and in none of them do I find any mention of the one great factor which will upset all your calculations, and render the aluminium jacket a failure in the hands of any but the most expert and careful of drivers. In other words, it is not "fool-proof," and for the following obvious reason, *i.e.*, *low melting point*.

There is scarcely a motor cyclist of over five years' experience who, at some time or other, particularly at dusk (when the phenomenon is most apparent), has not, on glancing down at his engine, particularly after mounting a long slope in a following wind, found that engine a dull, nascent red about the combustion chamber; and, moreover, the engine appears to be running well nevertheless. A glance at a table of melting points of various metals (to be found in any engineers' pocketbook) will show the melting point of ordinary commercial aluminium alloy (as used for crank cases, etc.) to be  $1,200^{\circ}$  Fahr., or only double the melting point of common lead ( $600^{\circ}$  Fahr.) So low, in fact, is the melting point of aluminium that it can be used successfully for "die casting"—an operation that can only be performed with metals of low melting point, such as alloys of zinc and tin, zinc and lead, etc., with sometimes an admixture of a little aluminium.

Glancing once again at our engineers' pocketbook, we find the temperature of a "dull sombre red" to be  $1,290^{\circ}$  Fahr. (Pouillet). Therefore, should an unfortunate or careless driver allow his engine to become a dull red on some summer evening, he will, on looking down to ascertain the cause of a sudden "seize up," find his beautiful aluminium *non est*; and, retracing his footsteps, he will discover various blobs of metal on the roadway that were once his fins.

It will, of course, at once be argued that with aluminium fins the engine could not possibly get as hot as a dull red, therefore the contingency will never arise. It depends on the driving, gentle reader. Some drivers will boil the water in the most ultra-efficient of modern cars, let alone melt aluminium fins off a cast-iron cylinder (when running on paraffin in these troublous days).

Finally, the whole idea is as old as the automobile industry. And had there been any real and lasting advantage in aluminium radiating gills, or had the commercial production

of the same been at all practicable, it is safe to assume that almost all air-cooled engines would have been so fitted. Success attended Lanchester's early air-cooled cars fitted with copper radiating gills, but commercial considerations caused the company to abandon the practice. It is extremely doubtful whether any juggling with various metals of varying heat conductivity, attempts at "oil-cooling," etc., etc., and other ingenious attempts to render air-cooling at all effective, will ever come within measurable distance (for real, right-down solid efficiency) of the most successful of all methods of cooling, *i.e.*, water-cooling.

E. V. HAMMOND, M.E.

**SIDECAR CONSTRUCTION.**

Sir,—I read in *The Motor Cycle* last week a remark on "streamline" sporting sidecars. I thought over the idea some time ago, and I drew out a number of designs, but none of them seemed to be easy to build (in theory). At last I hit on the idea of using either aeroplane construction for lightness or metal (pressed) for strength. The aero construction, wood and canvas, would be A1 for speed

The type of sidecar offering the least possible air resistance (and incidentally the least disturbance of dust) is of perfect streamline formation.

work on a track. "Swan" springing could be used and a simple frame in a sidecar of this type.

To take all the strain off the front of the motor cycle frame, the passenger would be seated slightly behind the sidecar axle, because the large front end of the sidecar would balance the passenger.

I am always interested in the discussions of "The Critics."

H. A. ROWE.

**REMINISCENT.**

Sir,—The photograph of Fountains Abbey (on page 593 of *The Motor Cycle* for 28th June, 1917) recalls two historical incidents which happened at this exact spot. Here, just opposite Robin Hood's Well (on left side of path), that forest freebooter bold Robin Hood and Friar Tuck carried each other backwards and forwards across the little stream. The hill shown in the picture, behind the figure reclining on the grass, is a gentle rise in the path, which encircles the ground, was the scene of the first bicycle hill-climb. This took place on the 26th of June, 1869, and I witnessed it "from within the ropes." There was a "great exhibition of bicycles and tricycles . . . with races." The machines were displayed in front of the Abbey (a reprint of the picture would be interesting). Wonderful and beautiful I thought the "boneshakers." Of course; there was not a wire wheel amongst them. I remember the details of that never-to-be-forgotten afternoon as clearly as if they took place less than forty-eight weeks ago instead of as many years. I was an inquisitive schoolboy at the time, and, seeing a knot of officials at the top of the slope, crossed the river at the top of the "falls" (see photograph), and joined them. I discovered that a special prize had been offered to anyone who could "ride up the slope" during the race round the grounds. Several reserved themselves for the effort. One got within a few yards of the top, then fell off. It was the first cycle (that word was not invented till quite fifteen or sixteen years later) race meeting I ever saw.

On the same afternoon the first bicycle race ever held in the City of London took place on the H.A.C. ground.

By the way, your contributor did not mention "the surprise" view of the Abbey. Visitors are taken through the grounds, upward and upward, but no sign of the ruins. Then they are assembled before a large double door. This is suddenly flung wide open, and "the most enchanting peep in all England" is before them. H. HEWITT GRIFFIN:

## INFLATION.

NOTES FOR THE TYRO  
ON THE PRESERVATION  
OF TYRES.

THE use or abuse of the foot pump is a matter with which the knights of our correspondence pages were recently juggling. Should I inflate my tyres board hard, semi-hard, or on the slack side, are the points discussed. Most correspondents seem to vote for the semi-hard degree of inflation, but surely something depends on the size of the tyres used and the weight of the rider and the machine. It also depends whether one measures hardness from the pedal cyclist or the motor car owner's point of view. Those enviably careful souls who always take their baths at one carefully measured temperature, probably inflate their tyres by the guidance of a pressure gauge, but the average motorist finds the toe of his boot, lustily applied, a good enough gauge. Therefore it would not be of much use setting forth the exact pressures (even if I knew them) to which motor cycle tyres should be inflated, and, moreover, this point depends on so many deciding factors that such a table might be only misleading. It is largely a matter of personal taste and judgment.

**Lightweight Tyres.**

During a wonderful assortment of riding on various machines—some, indeed, wonderful!—I have come to the following decisions on the subject: In the case of a lightweight having 24in. wheels, the tyres should be inflated just so hard that the rim does not bump on mounting at 20 m.p.h. stone setts which stand 3/4in. or thereabouts higher than the macadam, and no harder. In other words, do not pump the tyres any harder than is absolutely necessary to avoid rim contact, which should be "just impossible," and no more than just impossible. If 24in. wheels be ridden with the tyres harder than this, the discomfort and the general depreciation more than make up for the very slightly increased life of the tyre. This is especially the case on the war-worn roads which are only too common all over the country at the present time.

**General Depreciation.**

One correspondent very sensibly dwells upon this point of general depreciation caused by the jarring

effect of bone-hard tyres. It is an important point. The manufacturers of tyres, very sensibly and laudably, being anxious that their goods should give maximum wear, encourage riders to keep their tyres board hard, which is, of course, good for the tyre, since its walls are then subjected to much less bending strain, as the tread comes in contact with the road, than if the tyre were on the slack side. A slack tyre fluctuates with each revolution over the range of movement shown in sketch A, whereas a hard tyre moves only so far as is shown in B, therefore the wear at the points C is much greater in the case of the slack tyre than in the case of the bone-hard. This wear is communicated to the beading, which may split at an early date if the tyre be ridden too slack, and, moreover, if high speeds are indulged in, the constant depression and rebound of the slack tyre is apt to generate heat, and also movement of the inner tube, which may spell the destruction of old patches.

The relative strain imposed on the walls of a tyre loosely inflated and on one of normal hardness. It will be clearly seen that persistent under-inflation must soon damage both the wall and beading.

**General Rules.**

The rider of wide experience will invariably tell you that the degree of inflation at which he runs his tyres depends on what he is out for. If he is out for a gold medal in a strenuous six days' trial he runs his tyres almost (but not quite) board hard, and if out for pleasure he runs them at least 5° slacker. Running the tyres board hard may be good for the tyres, but it is wrong in every other respect. If a tyre be run in this condition it defeats its own aim—that of making up the inequalities of the road surface, and if it be found that a certain make of tyre persistently gives at the bead when ridden at a comfortable tension, then one's best plan is to eschew that make in future and try something fresh. Some makes of tyres, too, are apt to roll unless pumped up very hard, especially in the larger sizes. This gives a sense of insecurity to a motor cycle which is most unpleasant.

By riding one's tyres on the slack side the transmission and engine are relieved of many nerve-racking shocks, while one's comfort is enormously increased. A security valve is, of course, necessary.

B.

# QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

## Changing Gear on P. and M.

**Q.** What is the proper way to change gear on a P. and M.? Should the exhaust valve be lifted, or should the engine be slowed down with the control levers only?—E.K.

We have found the best way to change gear on the P. and M. is as follows: When changing up, lift exhaust valve at the same time as the gear lever is shifted, planting the lever well home with a sharp movement; drop exhaust instantly the gear is in. In changing down, keep the throttle open. Jerk lever from top gear position into neutral, allow the engine a brief interval in which to gain speed (not to race), and pull the lever up into the low gear position.

## Two-stroke Lubrication.

**Q.** I have a New Hudson two-stroke machine, and I am troubled with oil on the top of the cylinder. I have had cylinder head off, and find there is no gauze over the port hole. Should there be one in this machine? Also can you explain the reason of the following: It will run all right on low gear, and two-strokes splendidly, but as soon as the high gear is engaged it starts four-stroking, and gradually gives up entirely. Magneto is in good order, and the carburetter is a B. and B. automatic. Everything seems all right.—A.B.

No, the transfer ports of the New Hudson are not provided with gauzes.

You say you are troubled with "oil on the top of the cylinder," so from this it would appear that you mean externally. Evidently the oil comes from the decompressor. If you mean that you are troubled with oil in the combustion head, causing sparking plug troubles, etc., it is evident that you are over-oiling, and we should advise you to cut down the supply slightly. A transfer gauze does not prevent oil gaining the combustion space, but is merely to eliminate the likelihood of explosion in the crank case.

It is evident that your carburetter is fitted with too large a jet, and that the mixture is too rich except when the engine is running at high speed. You will have to ascertain the best size of jet by experiment on the road. We should say a 26 would be about right. Make sure that there is no air-lock anywhere—that the tank vent is not stopped up, and that petrol is reaching the float chamber easily.

## Wheel Speeds and Explosion Pressures.

**Q.** As an old reader of the "Blue 'Un," I readily turn to you to settle a few points, the result of a technical argument. (1.) Which part of the outer rim of a wheel travels quickest? (2.) Do wheels, running at high speeds, distort and become momentarily oval? I have seen a snapshot in a contemporary of a car travelling at a terrific speed, and the front wheels appear as distinctly oval. Are they distorted? If not, does the fault lie with the focussing of the camera? (3.) What is the pressure per square inch in the cylinders of a 2½ h.p., 3½ h.p., 5.6 h.p., and 7.9 h.p.?—H.T.

(1.) If you refer to a wheel travelling on the ground the top part moves fastest. It is, in fact, travelling at double the

speed of the car. The bottom portion of the wheel is, at the point where it touches the ground, stationary. (2.) No, a wheel does not distort at any speed. In a photograph of a car travelling at high speed the wheels appear distorted, owing to the fact that they have moved a certain distance in a horizontal plane during the exposure, while they have not moved in a vertical direction. The focal plane shutter also has the effect of distorting the image, as the bottom portion of the plate is exposed before the top portion. (3.) The explosion pressures remain approximately the same, whatever the h.p. This is not decided by the capacity of the cylinder, but by the compression ratio and throttle opening. The mean effective pressures are in the vicinity of 90 lb. per square inch, while the maximum explosion pressures lie between 200-300 lb.

## Wear in Carburetter.

**Q.** I have a Villiers two-stroke, with Senspray carburetter. Recently I dismantled the carburetter to clean it, and noticed that I could move the levers some distance before the corresponding parts in carburetter body moved. I tightened the wires, at the same time seeing that both valves shut when levers were in off position. On assembling and trying the machine a mysterious popping back through the carburetter occurred. This happens at all engine speeds if position of levers is suddenly changed, and especially if running slowly and with air shut right off.—D.K.S.

It is evident that one of the slides—probably the air—is not closing properly. The slides may appear to work freely when moved slowly with the engine idle, but the suction of the engine may have the effect of causing one or both of them to bind, entirely upsetting the mixture. It is possible that you will find wear in the barrels or in the carburetter body, and if this is so, it is very difficult to cure, and almost invariably means renewals ere perfect working is restored.

## Hill-climbing and Gear Ratios.

**Q.** I am running my machine on substitute (through a vaporiser) and find it knocks terribly on hills unless I shut off the air completely. (1.) What causes the knock? (2.) What is the maximum gradient that a 6 h.p. Enfield and a.c. in good order should get up on low gear and average load? (3.) What is the maximum speed advisable on low gear on a long hill?—J.R.

(1.) Experts are not agreed on the subject of knocking, but undoubtedly pre-ignition may be one of the causes. Paraffin and petroleum cause knocking more readily because they are ignited at a lower temperature than petrol, and thus pre-ignition is more likely to occur. (2.) The bottom gear of the machine in question is about 8½ to 1, in which case it should be capable of climbing a gradient of 1 in 4 or 1 in 5 with two up. (3.) Presuming that the bottom gear is 8½ to 1, then the speed of the machine with engine revolving at 2,000 revs. per minute would be eighteen miles an hour with 26in. wheels. It would be very inadvisable to exceed this speed on long hills, and on some hills it might even be an advantage to throttle down to twelve or fifteen miles an hour if the climb were exceptionally long.

**Difficult Starting.**

?

I am experiencing difficulty in inducing my  $3\frac{1}{2}$  h.p. Triumph to start. All it will do is to back-fire through the carburetter. I have just ground valves in, removed the carbon from the cylinder head, and cleaned the carburetter, but without any results. I should be pleased if you would give me your expert advice as to what may be the cause of the trouble. Do you think that having run on substitute has put any of the parts out of order? The magneto is apparently all right.—F.D.

It is probable that you have either upset the timing, or in reassembling the carburetter you have not taken sufficient care to see that the unions are air-tight. The use of substitute would not cause the trouble of which you complain, unless you have been using something in which there has been a great deal of water or other impurities. Water in the petrol system is, of course, fatal, and it is, moreover, very difficult to remove entirely.

**Crank Case Release.**

?

(1.) I have "Motor Cycles and How to Manage Them," also "Tracing Troubles," but they do not tell me how to economise in lubricating oil, and at the same time keep crank case, etc., clean on my  $2\frac{1}{2}$  h.p. F.N. I think oil is blown out past valve tappets and through bearings by crank case pressure. It seems to me that the little ball valve fitted is not half big enough for a crank case release. I should be glad to have your opinion. What is the objection to having a large breathing opening? On this engine it is on the top of crank case, between the valves. How would 2in. or 3in. of open tubing serve instead of the little valve, that seems to close just when it should remain open?

(2.) I have been troubled with strange misfiring after running ten miles; and sometimes after only two miles of fast running the engine begins to misfire, and gradually comes to a standstill. When misfiring begins, it gets rapidly worse on opening the throttle wider, and ceases if throttle is slightly closed.—C.M.

(1.) We do not think it would upset the running of the engine to experiment by fitting a breather pipe to the crank case; but if you do so, we would recommend you to carry it up to a good height, say about 4in., and bend it over at the top, so that any oil blown out would drop on to the ground. The crank case release valve does not need to be very large, as its object is to let air out and prevent fresh from entering, thus maintaining a partial vacuum in the crank case. We do not think you would really gain anything by trying to improve on the present release, taking it that the latter is working properly, and not choked with dirty oil. Your loss of lubrication is evidently due to wear in the tappet guides, etc.

(2.) As the misfiring occurs when throttle is open, it rather points to the fact that under full compression the spark does not jump the points of the plug. We should recommend you to try a new sparking plug, and to examine carefully the magneto and all electrical connections.

**A Mysterious Pulling Up.**

?

(1.) I have a  $2\frac{1}{4}$  h.p. Levis, fixed gear, with which I find this peculiarity. I start it off (it starts very easily), and, after going, say, four or five miles at a good speed, it suddenly pulls up, and, on dismounting and flooding the carburetter, it goes off for another distance, when the performance is repeated. The other day while out on this machine, as it slowed down preparatory to stopping in the usual manner, I happened to lift the exhaust, whereupon the engine blew back in the carburetter and immediately started again. I have since adopted the same plan, and it invariably sets things right. (2.) The engine will always misfire at irregular intervals, perhaps going a mile or so without, then starting again for twenty or thirty yards. Will you please give me your opinion on this?—R.E.B.

(1.) Try a smaller jet; also make sure that there is no air lock in the petrol pipe, and that air is permitted to enter the top of the tank *via* the stopper vent. Next time your machine begins to pull up, turn off the petrol and stop; then see if the petrol is at the correct level in the float chamber. If it is low, this will indicate that there is an impediment in the flow. Make sure the cylinder nuts and all the crank case bolts are tight. (2.) Most two-strokes misfire at intervals. The wrong sized jet, too much oil, a dirty engine, a gummed up top ring, or a partially choked transfer gauze (if one be fitted) will cause it.

**Damages and Garage Hand.**

?

I had a slight adjustment attended to at the local garage by the mechanic who was on the premises. The machine was a  $2\frac{3}{4}$  h.p. Douglas, and afterwards I asked the man to try the machine to see if anything else were wrong, as I had a long journey to go early on the following Monday morning. He did so, and collided with a wall in the yard, causing damage to the extent of £4 or £5. I at once saw his employer, who came and saw the damage, and he said the man was not in his employ after 6 p.m. The accident happened about 8.30 p.m. The employer therefore said he was not responsible, and the man and I must settle. The man said (in the presence of two witnesses) that he would get the repairs done. Since then I have received a letter from him saying he will, if I give him £2 towards the £4 which it will cost, proceed with the repairs. Feeling sorry for him I offered to help him to the extent of £1, as it has cost me very much more in train fares, loss of time, etc. He has again written me, and says he finds that he is not at all liable and will not do anything unless I pay half (£2). His argument is that I asked him to try the machine. Is he liable or am I?—F.A.C.

To succeed against the man himself you would have to show that the damage occurred through the negligent way in which he rode the machine. There ought not to be much difficulty about this, as the man was a mechanic and apparently

knew something about the machine. To succeed against the employer you would have to show, in addition to the above, that what the man was doing was within the scope of his employment; for instance, if it were not part of his duties to ride the machine to see if there were anything wrong the master would not be liable. Moreover, if the employer can substantiate his point that the man had no business on the premises after 6 p.m. it would be difficult to recover against the employer. From the letter it would appear that the man is liable for the whole of the damage.

**READER'S REPLY.****Dirt in Carburetter.**

I am interested in the difficulty of "Novice" in your issue of July 5th, as I had a similar experience with my  $2\frac{1}{4}$  h.p. Calthorpe. I think that if he follows your advice he will eventually trace the trouble. In my case the cause of the trouble was a small piece of solder which moved about in the tank. It was not sufficiently large to choke up the petrol flow to the carburetter entirely. When the machine was stationary it was an easy matter to flood the carburetter, and this put me off the scent for a considerable time. The mystery was ultimately solved when I undid the petrol supply pipe and discovered the obstruction almost covering the hole at the bottom of the tank. The suction of the engine once the machine was going would gradually draw the solder towards the top of the petrol supply pipe, and the inevitable stoppage would occur. It was an irritating bit of trouble, but apart from this I have found that my machine is of the utmost service to me and thoroughly reliable.—D. J. B. LEWIS.

# ABOUT MAGNETOS

Magnetos, to be satisfactory, must be manufactured on such lines as shall ensure absolute concentration of effort on every component part.

E.I.C. magnetos, besides being all British, are manufactured in such manner as to ensure the necessary concentration; thus accounting for their extreme reliability and efficiency.

The registered trade mark E.I.C. is to-day recognised throughout the motor cycle world as the mark which guarantees satisfaction on all matters pertaining to magnetos.

## E.I.C. MAGNETOS LIMITED

SAMPSON ROAD NORTH, BIRMINGHAM.

ON WAR SERVICE.

## The "GRADO" Paraffin Vaporiser

**Motor Cyclists!** here is a device which will enable you to run on paraffin and get results equal to petrol. It is designed by a practical engineer, and has been well tested. It fits between the engine and carburetter, and is connected to the silencer pipe by the clip illustrated. An injection of petrol through the tap on top starts your engine. Paraffin then does the work.

PATENT No. 13113.

*It is just what you require to-day.*

The price, all complete, is

**35/-**

POSTAGE 6d. EXTRA.

Delivery from stock. Order now, stating the outside size of inlet pipe.

## The "GRADO" Multi-Pulley.

PATENT No. 27485/13 and 6612/14.

Is simple in construction. Nothing to go wrong. Fits any standard belt-driven machine. Just half a turn of the handle changes from top gear to free engine. So simple.

Pulley fitted to machine.

Starts you like a car. The low gear gets you through traffic. The high gear saves fuel and gives you speed. The middle gears are there when you want them. The price, complete, for Triumphs, Bradburys, etc., is £3 3 0. Ball-thrust model, which we recommend, £4 0 0. Light-weight models from £2 10 0. Recessed Pulleys, 10/- extra. Postage, 2/- extra. Delivery from stock. Write for catalogue.

## THIS IS THE NEW MODEL The "GRADO" Heating Jacket.

PROV. PATENT No. 8124/1917.

This is the simplest and most effective way of heating the fuel. It does the trick in the right place. Simply fits over the carburetter, and allows of hot exhaust going all the way round it. There is no need to heat your fuel two feet away. Do it on the job by the "Grado" Heating Jacket. Made for A.M.A.C., Senspray, B. & B., Triumph, etc.

Price, complete, is 15/-, post free. State diameter of float chamber, or send carburetter and we will return with one fitted. Order to-day!

**GRADO MANFG. CO.,**  
Pershore Street, BIRMINGHAM.

*In answering these advertisements it is desirable to mention "The Motor Cycle."*

# MISCELLANEOUS ADVERTISEMENTS.

## PRICES.

**ADVERTISEMENTS** in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to **ILLIFFE & SONS Ltd., and crossed** & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

## NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

## DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Illiffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

## SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

## Enfield.

**ENFIELD** 6 h.p. Combination, 1916, splendid condition, all accessories, very little used; £80.—**Luther James, Hendrie Rd., Llangennech, near Llanelly.** [4887]

**ROYAL** Enfield, 8 h.p., 1913 machine, had little use, with cane sidecar, lamps, speedometer, etc.; £50, no less.—**College, 286, High Rd., Wood Green, N.** [X2705]

**1916** 8 h.p. Enfield Combination, mileage 500, lighting set, speedometer, Stewart horn; 90 gns.; no offers wanted; seen after 5 p.m.—**58, Woodfield Rd., Ealing, W.5.** [506]

**RIDER TROWARD** and Co., 31 and 78, High St., Hampstead.—**Enfield combination, late 1916, new, 34 gns.; 1915 3 h.p. twin, 32 gns.; 1916 2-speed, 2-stroke, 29 gns.** [5521]

**ENFIELD** 1915 6 h.p. Combination, used once since June 1916, three new 650 x 65 covers and tubes being fitted; £65, first-class condition.—**Victoria Villa, Wellesley Rd., Clacton.** [X2693]

**ENFIELD** 1917 2-stroke, £44/2, brand new. We are Enfield specialists. Both models in stock; immediate delivery.—**Wilkins, Simpson, and Co., 11, Hammersmith Rd., London.** [5326]

**ROYAL** Enfield 1916-17 3 h.p. Twin, mag., 2 speeds, kick, dynamo lighting, as new; 45 gns.; exchanges entertained.—**Wandsworth Motor Exchange, Ebner St., Wandsworth (Town Station).** [5467]

**NEW** Enfield, 2 h.p., 2-stroke, 1917 model, 2-speed gear, chain drive transmission; £44/2 cash, or 2% extra for easy terms.—**Wanchope's, 9, Shoe Lane, London.** Phone: 5777 Holborn. [5405]

**6 h.p.** Enfield Combination, 1915-16, guaranteed perfect condition, Lucas lighting, speedometer, spare chain, tools, etc.; any expert examination; £70, a bargain.—**Apply, E. Langdon, Exmouth, Devon.** [5183]

**ENFIELD** 1914 3 h.p. Twin, 2-speed, kick starter, accessories, spares, petrol, and 20 gallons good substitute, fast, economical, perfect condition, little used; trial; £35, no offers.—**98, Tulse Hill, S.W.2.** [X2620]

**ENFIELD** 6 h.p. Combination, handsome coachbuilt sidecar, speedometer, and all the best accessories, very powerful twin-cyl. engine, with tools to complete, 70 gns.; also another combination, same make, 6 h.p. twin, and sidecar, 60 gns.; both machines guaranteed mechanically fit, and smart appearance.—**Wruchope's, 8, Shoe Lane, London.** [5403]

**ENFIELD**—We have actually in stock on the premises 1917 2 h.p., 2-stroke, 2-speed, £44/2; also 1917 combination, standard model, S.H., with accessories, £89/10; also 1913 coach 4 h.p., and another combination, like new, 1917, 50; easy payments or exchanges.—**Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green.** [5535]

## Excelsior.

**EXCELSIOR**, good old X; delivery from stock.—**The Premier Motor Co.**

**STANDARD** Model, 7 h.p., 3-speed, £75; De Luxe Model, with dynamo lighting outfit and speedometer, £85.—**The Premier Motor Co.**

**SPECIAL** Sidecars for above, enamelled to match, 28 x 3 in. tyre, etc., £15 and £19; liberal exchanges, trial run.—**The Premier Motor Co., Aston Rd., Birmingham.** [5373]

**EXCELSIORS**—All models in stock; magneto model £75, electric lighting model £85; get a big X. You'll be satisfied.—**Colmore Depot, Birmingham, Manchester, Liverpool, and Leicester.** [X1462]

## Forward.

**FORWARD**, 2 h.p. twin; £22.—**W. and H. Motor Co., Ltd., 287, Deansgate, Manchester.** [5280]

## F.N.

**RIDER TROWARD** and Co., 31 and 78, High St., Hampstead.—**1913 F.N., 2 h.p., 2-speed, clutch; 16 gns.** [5522]

**F.N.**, 4-cyl., genuine late 1913 model, 2-speed, hand clutch, electric lighting, Lucas horn, new tubes and tyres, cylinders recently rebored, fast and powerful, guaranteed mechanically perfect; further particulars stamped envelope; exchanges; set £30.—**Box 1,069, c/o The Motor Cycle.** [5345]

## Hamilton.

**1913** 4 h.p. Hamilton, 2-speed, F.E.K., C.A.V. mag., B. and B. Dunlops, Saxon fork, good powerful machine; £25.—**Gill, Fold Farm, Grindleford, Derby.** [5480]

## Harley-Davidson.

**NEW** 1917 Harley-Davidsons in stock; only one of each model left.—**Below.**

**1916** 7 h.p. Electric Harley-Davidson Combination, in perfect order and condition throughout; £89.—**Elce and Co., 15-16, Bishopsgate Av., Camomile St., E.C.3.** [0551]

**RIDER TROWARD'S**, 31 and 78, High St., Hampstead.—**1915 Harley-Davidson standard combination; 65 gns.** [5528]

**HARLEY-DAVIDSON** Combination, 1915, Bosch, electric lighting set, many spares; £65, nearest.—**31, Gible St., Wolverhampton.** [X2627]

**COLMORE** Depot, Birmingham, Manchester, Liverpool, Leicester, for immediate delivery of all models of Harley-Davidsons, and spare parts. [0802]

## The Hottest Part of an Engine.

ON another page we print extracts from a most interesting and instructive article which appeared in *The Autocar* of July 14th entitled "The Hot Spot on the Piston." The subject of piston cooling has been considered in our pages on more than one occasion recently—in fact, it formed the subject of an article in last week's issue. If the piston can be cooled from within by fresh air being constantly taken into the crank case so much the better, but it is obvious that it will be more advantageous to allow the centre of the piston head to remain hot than to cool it by means of the oil which is expected to lubricate the bearings of the engine.

It is not generally realised that as the oil constantly impinges upon the inside of the hot piston head, it becomes very much heated, to the great detriment of its lubricating qualities, and a considerable amount is carbonised inside the piston. Some of this carbon drops off into the interior of the engine, and forms with the lubricant a mild abrasive which cannot be good for the bearings. From this we see one good reason for emptying and swilling out the crank case at frequent intervals.

What heat the piston loses is dissipated almost entirely through the rings and cylinder walls; the air and oil in the crank case was proved by Prof. Bernard Hopkinson, of Cambridge, to have an almost negligible effect—that is to say, the piston was only 2% hotter when deprived of the advantage of these aids. We presume, however, that the experiment was conducted with an engine unprovided with a cooling blast within the crank case. We may infer, therefore, that the disadvantage accruing to the oil from its contact with the piston far outweighs any advantage which the piston may gain from the cooling power of the oil.

Fortunately an engine can run for hours with the centre of the piston head in a state of very considerable heat, and consequently it may be

cut off from the interior of the crank case and contact with the oil by a baffle plate situated just above the gudgeon pin.

Several motor cycle two-stroke engines have pistons designed in this manner, but, curiously enough, the inventors had quite another object in view, viz., increasing the crank case compression, and the great advantage to be gained by keeping the oil from the underside of the piston head seems to have escaped them entirely.

## More Economical Carburetters.

PROBABLY for years to come fuel economy will be a deciding factor in the success or otherwise of any new carburetter design. The present-day carburetter is a peace-time production, in which economy has by no means been ignored, but while petrol was plentiful the miles per gallon were not so important as they are destined to be in the future. A slow tick over, together with rapid and smooth acceleration, were perhaps foremost in the mind of the carburetter inventor, though of course consumption was not neglected.

It has generally been taken as an acknowledged fact, however, that those other properties so highly desirable for the comfortable touring machine must be forfeited, partly or wholly, if abnormal consumption figures are required, but there is no doubt that if the order of things were reversed, if the carburetter inventor started off with the fundamental basis that he must have economy, he might produce something far more economical than he has produced in the past. The problem, then, to be solved would be how to obtain smooth running and the other advantages we have named, in addition. At all events, there is no doubting that an enormous market awaits the truly economical carburetter—even if that extra 20 m.p.g. be obtained at a slight loss of flexibility—and it is to be hoped that the carburetter industry, which has by no means shown itself lacking in initiative in the past, will rise to the occasion without delay.

## A PLEA FOR SIMPLICITY AND LIGHTNESS.

**T**HOUGH much ink has been spilled on this topic, we do not seem to be getting much nearer to our objective, the evolution of a really sporting motor cycle. The trouble seems to be that everyone uses the word "sporting" in a different sense. The selling agent christens all crude and uncomfortable conveyances "sporting turnouts." To manufacturers and their expert riders, "sporting types" suggest T.T.'s, records, and big advts. I submit that "sport" is little concerned with mere speed lust and utility, and has *nothing* to do with trade.

Now sport and sportsmen are as various as life; but all sportsmen distrust the armchair theorist. It may be well, then, to make it clear that the present writer has had an exceptionally varied experience of field sports and sporting games, and has been "useful" at most of them. Though the following theory rather "smells of the lamp," it has been tested in football scrums, on mountain tarns, and on Canadian rivers. It is now recognised that for periods estimated at from four to eight million years before ploughing and sowing, buying and selling, were invented, men with brains like our own fought and courted, hunted and wandered, over the Thames Valley. I submit that "the sportsman" is the primitive river-drift and cave-man's modern representative, that he is the *normal* man, unspoilt by a few thousand years of artificial life.

### The Travel Tools of Primitive Man.

All our sports, then, derive from man's deepest instincts; but with all respect to our D.R.'s (good luck to them), to fishermen, and "sidecarists," it is plain that the "sporting type" of motor cycle is the mount of the modern wanderer—"the man of the open road."

If we want a conveyance which will gratify this deep-seated wander-lust, let us take a glance at the essential points of the "travel tools" of primitive man. An Esquimau kayak (canoe), a sledge, or a pair of snow-shoes, has three common main features. (1.) Skilful design, and the employment of *flexible materials*, achieve a wonderful combination of strength and lightness. (2.) All can be quickly adjusted and repaired, thanks to the choice of material

and simplicity of design. (3.) None of them are designed to be fool-proof, but all respond perfectly to skilful handling. The importance of No. 2 is now recognised, and need not be further insisted on. But No. 3 helps to give a freer hand to the designer of a "sporting type." No. 1 seems, however, so vital that, at the risk of presumption, I venture to urge its importance on seekers for a really sporting motor cycle. Is it essential to cage a large and savage engine in a ponderous frame, and then to add further weight and complication in the form of springs, so as to save rider and conveyance from early dissolution by "road shock," and a kick-starter to get the monster to move?

### Suiting the Means to the End.

Let us go back to primitive and sporting ideas. The sportsman-wanderer desires, as do all sportsmen and primitive folk, a nice adjustment of *means to ends*. Who wants to kill trout on a salmon rod, or shoot pigeons with a 4-bore? Cannot some sportsman-engineer provide us with a small, light, and smooth running *engine* of essentially simple design (e.g., a valveless flat twin two-stroke whose alternately driving cylinders would scavenge and charge each other)? A *transmission* which made a long range of infinitely variable ratios available on direct drive would enable the engine to be run normally at its most efficient rate of revolution, leaving throttle and spark in reserve, and so economise power and weight. Such an engine could safely be housed in a very *light spring* (not sprung) *frame*, i.e., the main frame members could

*themselves* be resilient. The outside flywheel might house the source of both ignition and light. These detailed suggestions of a mere sportsman may seem to the engineer—and probably are—amateurish, but I venture to claim that the *essential*

A motor cycle designed by the author of the article, who strongly advocates the reduction of weight in making what he terms a "sporting" type of mount.

features of primitive travel tools—*strength, lightness, and flexibility*—are the key to the problem of the sporting motor cycle. That this antique "flint arrow" may strike a spark of genius from the steel of some courageous modern designer is the fervent hope of the writer.

A. POTT-HUNTER.

# Occasional Comments by "Ixion"

## Composite Engines.

IT is getting pretty evident that the engine of the future is going to be a hotch-potch of parts made of different metals. I am thinking of the upper half of the engine, for, of course, designers have long enjoyed great freedom of choice below the waist belt. Everything points to aluminium cooling ribs, fitted on to a separate cylinder barrel, possibly of steel, with perhaps an aluminium alloy piston, and certainly overhead valves. Anybody who has handled one of these composite engines will understand that the next crux will relate to the metal of which the cylinder head will be made. Cast iron is the usual medium at present; it weighs a good deal, it gets very hot, it consequently leads to the maximum pitting of the valves, and the most rapid weakening of the springs, and it distorts sadly. What will it be made of eventually? Cast aluminium alloy with iron valve seatings? The clumsiness of these loose heads, as contrasted with the delicate machining of a turned steel cylinder or the low weight of an aluminium cast cylinder, is the point which strikes an observer first and hardest in his comparisons.

## Standardisation in America.

ON June 14th the American motor cycle manufacturers met to consider how far it was possible to meet the demands of the War Department by standardising the parts of motor cycles constructed for war service, and so to reduce the stocks of spares carried at the various army depots, accelerate manufacture, and simplify repair work. The manufacture of motor cycles and of motor cars differ fundamentally in America. There is probably not a motor car chassis made in the States, excepting only the Ford, which does not include components made by some specialist factory, and found also on dozens of cars emanating from other firms. The number of component parts, shared with other cars, drops to perhaps half a dozen in the case of a car built by the thousand, such as the Overland, and rises to hundreds in the case of the smaller concerns. But in the American motor cycle trade, as in our own, the average machine is made from stem to stern in a single works, and includes hardly any standardised parts at all. The meeting finally agreed to standardise the following parts of the W.D. cycles: rims, spokes, tyres, sparking plugs, head light, mountings, magneto bases, chains, controls, clutch pedals, brake pedals, gear shifts, kick-starters, oil and grease cups, oil and fuel pipes, and unions and taps, sidecar connections, and other sidecar fittings. There is not the least reason why a similar standardisation programme should not be devised and carried through in our own trade, and it would enormously simplify problems connected with our export trade when the war is over. Only about three of the above items are as yet properly standardised.

## Oiling a Flat Twin.

CHINOOK'S " remarks on oiling a flat twin only apply to a strange mount, or to a haphazard driver. The ordinary motor cyclist adopts some sort of system with his own mount, and when he puts it away for the night he has so arranged matters that the crank case contains a normal amount of oil, sufficient, let us suppose, for five or six miles. On next starting out he continues to oil according to routine, and the colour of the exhaust does not affect him a whit. As a matter of fact, most flat twins, being distinctly *fin de siècle* machines, have rather more refined oiling systems than the general run of machines; for example, the one which I rode to-day has two oil level taps to the crank case, a maximum and a minimum, as well as a sight glass for the oil feed. Nor have I found in actual practice that the ordinary flat twin is peculiarly apt to smoke when it is first started up. It is true that such oil as its cylinders contain prior to a stoppage is likely to remain there when the machine is at rest; it is equally true that many singles and V twins have oil wells on the top of the crank case, whence any oil drainage is collected by the first dip of the piston on restarting. There are, of course, exceptions in both classes: but taking them in the lump, the flat twin may be treated in this respect just as if it were a single.

## The Dummy Piston Head.

MOTOR cyclists will probably take a special interest in the Hatch patents, discussed in *The Autocar* of July 14th. The notion is that oil is wasted and carbonisation accelerated by the great heat of the piston head, presumably the hottest part of an internal combustion engine. Now there is obviously no reason why oil should ever reach the lower side of the piston head; and if we can prevent this without introducing counterbalancing faults, our oil will keep cooler, we shall get more work out of it, and carbon will form much less slowly. Nobody suffers more from oil wastage and carbon deposits than the motor cyclist, and I hope our post-war engines will prove to be fitted with something on these lines. The carbon deposits inside the piston are the hardest to get rid of, and many owners leave them untouched world without end. It is usually impossible to remove them without taking out the gudgeon pin, a job from which the ordinary amateur is apt to shrink, and not without reason. However, *The Autocar* goes so far as to say that the inside of the piston really acts as a little roasting oven for the oil; that the carbon so formed is mildly abrasive in character, and that it helps to wear down our bearings, besides wasting our oil. The piston of the average baby two-stroke gets extraordinarily crusted with carbon on the inside of its head in a very short time, and if these deposits are allowed to accumulate smooth running is impossible.

## ENGINE AND GEAR BOX AS A UNIT.

The Pros and Cons for the Unit System of Construction for Motor Cycles, which, when properly applied, has many things to recommend it.

IT is difficult to draw a line between the points at which repetition ends and invention begins, and if the system with which the writer proposes to deal has originated since the birth of the motor cycle, then certainly British engineers originated it. At any rate, we in England were the first to adapt the unit system to motor cycles, but while, in this country, the system has met with little success, it has, in America, marked the whole trend of motor car design, and is quickly creeping into motor cycle practice. The Cleveland and the Henderson are two good examples, and incidentally mark two extremes; I do not necessarily hold up the design of either of these machines as ideal; indeed, certain British units are illustrated herewith which probably surpass them, yet with the exception of one or two lightweights the system is nowhere popularly established over here as it is in the States. Years ago our makers produced designs which

An early Veloce design, in which the makers still retain considerable faith. In many respects the unit was considerably before its time, oil being pump fed under pressure to the main bearings, while the oil sump was integral with the crank case. Note also the outside flywheel. The design of the unit was such that a long, low-speed belt was employed, while the two-speed gear was operated by metal-to-metal cone clutches, operated by heel and toe lever. Though neat and ingenious, the unit was never a commercial success. The engine was  $2\frac{1}{2}$  h.p.

The Precision Junior unit, in which space and weight are economised by the employment of a central shaft which answers the dual purpose of camshaft and intermediate shaft of the two-speed gear. No clutch is fitted in this diminutive unit.

promised wonderful development, but because they were before their time they were turned down by the purchasing public.

### Where the Integral Unit Scores.

What are we aiming at in motor cycle design? Foremost come simplicity, neatness, reliability (a minimum of adjustment and of wear), a clean and compact exterior, a well protected and well oiled interior, lightness, and accessibility. Dealing first with the advantages of the single unit system, let us take these talking points in order.

(1.) SIMPLICITY.—A design which calls for an absolute minimum of adjustment is the simplest. In popular present-day design, in which we have the engine amidships, the gear box separately suspended a foot to the rear, having its own adjustment and its chain drive, the magneto thrown in where it fits, and likewise having its driving chain adjustment, we cannot claim simplicity. We have here various adjustments, and by minimising the necessity for adjustment we

## Engine and Gear Box as a Unit.—

The Henderson is a neat and interesting example of integral unit design. The unit comprises engine, three-speed gear box, clutch, magneto, carburetter, induction pipe, and silencer, all of which can be dropped out of the frame as a whole. Practically any working part inside the crank case can be adjusted or replaced by turning the unit upside down and detaching the lower half of the crank case. Inspection doors are also provided, so that the engine and gears can be examined in the frame.

minimise the likelihood of breakdowns which are the result of neglect. In the integral unit system adjustments are reduced to a minimum.

(2.) **NEATNESS.**—In this respect the integral unit system is so obviously superior that we need not dwell upon the point.

(3.) **RELIABILITY.**—This is partly covered by the first heading. By eliminating adjustment, reliability is increased; and, further, by ensuring fresh lubrication fed at a regular speed to all hard-working parts, reliability and reduced wear are ensured.

(4.) **A CLEAN AND COMPACT EXTERIOR—A WELL-PROTECTED AND WELL-OILED INTERIOR.**—As regards

The Scott Sociable two-stroke unit departs from standard practice almost throughout. Its specially designed cone clutch occupies a purposely inaccessible position inside the flywheel, the drive being by skew pinions to the gear box on one side and the water pump and seat-starting mechanism on the other. From the gear box the drive is by enclosed shaft to the rear wheel.

appearances, the more modern designs here illustrated speak for themselves. Many of them are a joy to behold as regards compactness and neatness. The lubrication for the transmission is, of course, fed from the engine, so that so long as the engine obtains its oil the remaining important parts are certain of their share. The oil may be fed from the engine through the clutch to the gear box and final reduction gear, the overflow, or release, being situated at a correct level at the rear end of the unit. Thus, in the case of a four-stroke, all the important bearings can be pressure fed throughout the system by crank case compression. Some riders may object to having their clutches locked up in any way, but here it may be pointed out that the ingenious designer of the Scott Sociable has purposely placed his clutch in such a position that the owner of the vehicle cannot get at it. This is rendered possible by the employment of a design of clutch which cannot require attention, and

The Villiers four-stroke unit was remarkable for its exceedingly clean exterior. A silent chain was employed from engine to countershaft, the clutch being inside the countershaft chain wheel. This 2½ h.p. four-stroke was abandoned four years ago. Note the entire absence of protruding shaft ends.

if the clutch be designed to occupy an inaccessible position, then by all means shelter it from restless fingers. As for cleanliness, the single unit has it every way. It has fewer joints, no oil-clinging chains, and a minimum of exposed bearing ends. The Jowett light car engine is the cleanest I have come across.

(5.) **LIGHTNESS.**—The system offers the possibility of a reduction of weight, because it does away with countershaft chains and sprockets, the drive being direct from engine to gear box, but this advantage would be very slight.

With accessibility and cost of production I intend to deal later.

#### A Unit braced in itself.

We have here several strong talking points in favour of the single unit system, but there is yet one more. By the employment of this system the frame can be

### Engine and Gear Box as a Unit.—

The Diamond power plant, which has figured successfully in public competition, was originally designed in 1911. In the top illustration the cover is removed, leaving transmission *in situ*. A double cone clutch is situated between the engine and gear box, the two gears being obtained by the employment of dog clutches on respective sides of the bevel pinions.

Note the layout of timing gear, also enclosed overhead inlet valve mechanism. The engine is  $2\frac{1}{2}$  h.p.

considerably lightened and simplified—in fact, it can be reduced to truly scientific lines. An integral unit is braced in itself and self-contained, instead of the stresses being thrown about haphazard. It can be slung under the frame by two points of contact, which are placed at the apices of the frame triangles, and thus it will be obvious to any engineer that both its method of suspension and its self-containedness would not only adapt themselves to an ideal frame design, but also they would tend to minimise vibration.

So much for the advantages of the system, with which the article is primarily intended to deal. Various “disadvantages” have been pointed out, but

The two-cylinder two-stroke Premier, in which piston rods are substituted for the conventional connecting rods, the big end bearings being fitted with slides in which are carried the flat feet of the rods. The longitudinal drive is transferred to the transverse direction by means of bevel gearing, while another bevel is used to drive the magneto. The gear wheels to provide three ratios are carried on the main cross shaft, while the lay shaft is directly beneath it. The six wheels are always in mesh, and engagement is obtained by means of balls in the hollow shaft, which are pressed outwards into half spherical sockets in the gear wheels.

most of them appear to be based on past designs, which were clearly undeveloped rather than to be inherent defects inseparable from the system. The disadvantages claimed are: (1.) That the man who makes the engine does not make the gear box. (2.) That a worn bearing in any part of the unit causes the defect to be felt throughout the mechanism, and is difficult to replace. (3.) That in order to get at anything, barring the cylinder, one has to drop the whole unit out of the frame.

Again I will deal with the points in order. No. 1 is the first real

Showing the transmission of the Swift unit with the gear box inspection cover and half the worm gear casing removed.

stumbling-block as yet, but in these days of self-aligning bearings half the difficulty is removed. Given a simple design of gear box the manufacture of the pinions, etc., presents no difficulty, all bearings throughout being of the self-aligning type.

No. 2. I see no reason why a loose bearing should affect the whole unit, for there is positively no reason why the units, though contained in the same case, should not be as independent of

each other as they are in the popular “scattered” design. I can find no better word for it. A slack fitting castellated connection or dog clutch between clutch and gear box is, of course, desirable.

**Engine and Gear Box as a Unit.—**

No. 3 appeals as another objection of the milk and water type. We take it that in the ideal integral unit system the whole bottom half of the casing will be in one piece, the joint being midway, while the top of the casing is provided with large inspection plates. A defective bearing means, in any case, a good deal of work—probably a general inspection, so why not drop the unit out of the frame and do the thing properly. The integral unit adapts itself to a very simple method of attachment, and by removing the top half of the casing the whole gear box, etc., would be revealed, the self-aligning bearings could be removed, and a thorough inspection made throughout.

I may be suffering from a mental obsession; if so, I tender my hearty apologies to all readers of *The Motor Cycle*. To the journalistic mind the single

The Clyno two-stroke unit is so well known as to call for little comment. A slightly longer belt is obtained than would be possible with the step drive, and, in addition to the two-speed gear, the unit includes a multiple-disc clutch operating direct on the pulley.

unit system makes a strong appeal on account of its simplicity, its rigidity, its grit-excluding properties, and its cleanliness. Why it has not developed over here is—in my humble opinion—because the British motor cyclist is either too much of a conservative or too little of an engineer to realise its possibilities. He does not purchase a machine on the strength of the salesman's "hot air." Having heard the salesman through he goes home determined to discount every word he has heard, and finally he buys a belt-driven single, because his cousin, three years ago, obtained very satisfactory service from such a mount. Before the war invention over here was a chilly game, and though there is much more I would like to say

about the single unit system, one dwells, in these days of paper scarcity, in mortal dread of the blue pencil.

CHINOOK.

## D.R.'s AND THEIR WORK.

(IN FOUR INSTALMENTS).

### I.—TYPES OF DESPATCH RIDERS.

BY D.R.

**W**HEN the war broke out motor cyclists were invited to offer their mounts and their services to their King and country. At the time there was little attempt made to ascertain whether the recruits were experts or the merest novices, or to fix fair prices for any machines taken over by the Government. Consequently some terrible "wash-outs" were engaged, and their machines were taken over at ridiculously high prices. A pioneer of the very earliest motor cycling days might wish to serve, but he would be turned down because he and his mount both looked too old. This man might eventually have to serve as a private in an infantry regiment because he still happened to be under forty. On the other hand, adventurous youths with very little experience were taken on and provided with new machines. Some of these have since become hard and expert riders, but others never will become experts until the war is over and they realise the cost of keeping their own machines in repair. Any artificer in the Service will immediately recognise the type of youth to whom I am referring.

Next we got the theoretical motor cyclist who knew all about every motor bicycle on the road from reading about it! He was seldom seen without a bundle of motor papers or manufacturers' catalogues or hand-books. He could tell you the c.c., speed, revs. per minute, weight, price, fittings, equipment, etc., of any machine you could mention. But he had never

owned or ridden any of them. When it came down to actual practice he was only a little better than the type of D.R. last mentioned. He at any rate had some idea as to how a machine *should* be ridden and cared for, whether he could do it or not.

As time went on we arrived at the "Lord Derby registration paper" and "combing out" stages, and then we got a wonderful assortment, from the true sport and patriotic Britisher down to the funk who wished only to evade the trenches.

### The Best Type of D.R.

There is another type of D.R. not included in the above scathing criticisms. He is the gentleman and a true sport. He was always keen on motor cycling as a hobby, and always kept first-class machines in first-class order. When the time came it was quite unnecessary to tell him that his King and country needed him. He knew it. He enlisted as a D.R., and did any kind of work allotted to him without grumbling, and always took as much care of the machine entrusted to him as if it were his own. He may still be doing the most dangerous work and living under the greatest hardship. He may have succeeded in getting a commission and now be using his authority gently, but firmly, over the other types of D.R.'s I have mentioned. Or he may have graduated to the Royal Flying Corps and done good work in that branch of the service.

## OVERSEAS SECTION.

### A Commentary based upon Practical Experience and a Study of Overseas Opinions.

**The Future of the Four-cylinder Motor Cycle.** ONE seldom comes across the rider of a modern four-cylinder motor cycle who has anything but praise for it, and there is no doubt that a big future awaits this type of machine. Its unique pulling powers at low speeds, combined with cool running, render it particularly adapted to Overseas requirements, while it is capable of attaining a rate of revolutions which is attractive to the speed man. It lends itself particularly to a positive form of drive, to the elimination of chain cases and adjustment, and to the integral unit system by which the gear box and clutch are contained in a grit-proof housing adjoining the crank case, thus ensuring perfect lubrication throughout. The majority of British manufacturers have not, at the moment, very much opportunity of experimenting, but in many leading factories one finds on the drawing boards entirely new designs which are to materialise when conditions permit. Among these the four-cylinder figures conspicuously, while clearly there will be no dearth of flat twins from leading factories. The majority of the "fours," however, will be primarily designed for sidecar use, though this in no way signifies that they will be cumbersome for solo riding. On the contrary, the majority of the British fours will be a good deal lighter than the American four, which has already attained a fair degree of popularity Overseas.

✻ ✻ ✻

**Are Chain Cases Desirable?** RECENTLY we were discussing a certain Russian military model with a group of Australians. The unhappy mount reviewed was fitted with chain cases in place of a simple chain shield which had previously characterised this make. The chain cases were good, substantially anchored and solid, but our Australian friends condemned their presence—almost to a man. "If I had that machine over there," stated one of them, "I should have those cases off within a fortnight—if I didn't take them off before riding the machine home!" This state of affairs is distressing. The manufacturer knows that chain cases are good for the Overseas rider, and, accordingly, he is spending much time and money in perfecting them; but is it only to have these luxurious fittings left at the roadside or poked into a rabbit hole when the machine reaches its destination? Our own experience of enclosed chains is that, provided sufficient ground clearance be left in the vicinity of the countershaft, they are entirely satisfactory, and it must be borne in mind that their presence adds enormously to the life of the chains and sprockets. The life of a properly encased chain transmission is, indeed, almost endless.

#### Fostering British Trade Abroad.

THE New Zealand globe trotter, Mr. J. B. Clarkson, is in England again, and for the last fortnight has been busy doing the round of English motor cycle manufacturers. On the occasion of the present visit he was invited to attend a meeting of motor cycle manufacturers with the idea of discussing Overseas trade, to which he gladly assented. The meeting was a private one, so we are unable to pay more than a passing reference to it, but we are glad to think that British motor cycle manufacturers seized the opportunity of obtaining from Mr. Clarkson first-hand knowledge of the condition and requirements of certain of our Overseas markets. We only wish that it had been possible for *all* manufacturers directly concerned in Overseas trade to have been present. Collaboration of this kind—even if everyone may not see eye to eye with Mr. Clarkson—cannot but do good to the industry at large, for only by a frank discussion of our mistakes of the past are we likely to be able to exploit to the full the possibilities for British motor cycles in countries abroad.

✻ ✻ ✻

#### Clutch Control.

It has always been a matter of some mystery to us that the Americans, who have often advocated control accessibility, should have stuck unwaveringly to the tank clutch lever in preference to the handle-bar lever. Our own experience of country roads in the States is that the handle-bar clutch is the very thing above others that one is left craving for. We recall one ride in particular when, mounted on a well-known make of American machine, our way led along a trail which, at certain points, was deep with black slime, and the transmission being a trifle harsh, the only way to get along at all was by constant clutch slipping. Neither the pedal nor its position was particularly well adapted to the work. On account of the rough going one was compelled to stand hard on the footboards, with the result that one's left foot was fully employed. The control necessitated supporting one's weight on one's heel and manipulating the clutch in the best way possible with the tip of one's toe. The result was that one lacked that delicacy of control which makes all the difference in the manipulation of a clutch. One gets used to the foot clutch, of course, but that the handle-bar clutch is infinitely superior to the pedal variety is maintained by our D.R.'s, one of whom openly states that no machine is fit for use under the conditions of warfare unless fitted with a h.b.c. clutch. The ideal system is an inter-connected hand and foot control for the clutch, such as many British makers now provide.

**All-British—** Thus ended the proclamation of the "No More natives on the annexation of a certain um Kaiser!" German possession in the Pacific, and so say all of us—"No more um Kaiser!"

The British magneto of to-day is a top notch article, surpassing in quality the much-quoted instrument of Kaiserland, and each week recently our letter bag has brought us comments from riders all up and down concerning the excellent treatment received from British magneto makers. Momentarily diverting—some of the British magnetos produced early in the war were admittedly inferior to the Bosch. This was on account of the absolute lack of materials, on which the vitals of the magneto depend, and upon other difficulties of manufacture too numerous and complex to discuss here. Since then our chemists have been at work, and trade has developed, and now before us behold the British magneto, the instrument employed by every aeroplane, motor cycle, and motor boat produced for the British Forces! And, as Britain stands on her own legs for magnetos, so she is self-supporting for the various other accessories and gadgets previously hailing from Kaiserland. After the war the patriotic purchaser will be able to demand a machine which is all-British from end to end down to the smallest accessory. The enormous advancement that has been made can only be appreciated by those in constant touch with trade affairs; we have left the Huns standing as regards accessories, and so with the patriotic Kanaka of the South Seas we exclaim, "No more um Kaiser!"

**British Exports of Motor Cycles.** **ALTHOUGH** all motor cycle manufacturing firms are busy on munitions, we continue to develop our Overseas trade to an extent satisfactory under the circumstances. It is indicative of what the future may hold for exporters, when in the midst of war we can send out £80,951 worth of motor cycles and parts in one month, as was the case in June. A good deal of comment was heard on the rather large drop in British exports for June as compared with May, nearly every industry showing a decrease. One of the exceptions was the motor cycle export figures, which showed an increase of £20,000 on the previous month. The figures for the half-year 1917 show that we exported motor cycles, parts, and tyres to the value of £438,747. This is an increase on last year's figures of £58,131, and on the 1915 returns of £97,589. Compared with pre-war times this year's figures are only slightly under those for 1913. Certainly in 1914 there was a big jump of £159,520 over the six months of 1913, but when the great upheaval of the industry is taken into account, and a moment's thought given to the adverse circumstances under which foreign trade is at the present time being fostered, it is surprising and gratifying to observe how well we have maintained our connections abroad in the third year of a great war.

### American Competition Again.

R.E.H., AUCKLAND, N.Z., writes: "This is just a letter to make our usual New Zealand complaints. Yankee cars and motor cycles are having a great run now, mainly on account of their low prices.

"The Indian offers a special inducement in addition to low price—a spring frame and good clearance, both of which are indispensable. Of course a machine like the Bat has a better spring frame and general appearance, but the price—it makes one weep to contemplate the difference. A local agent has just unshipped two motor cycles—a 5.6 h.p. Ariel and a 9 h.p. American Dayton. Both are equally well off in specification. Each has a spring saddle pillar, but the Dayton has a better appearance, being finished in dark red. The price of the Ariel is £105, Dayton £85.

"Many would prefer the Dayton, apart from the price, with its good springing, mudguarding, and clearance; but the Government are not inclined to use Yankees. They have a large number of Enfields with sidecarriers, which they use for collecting mails in the city and suburbs from the pillar boxes and for delivering letters in some of the outer suburbs. I will send you a photograph of one if I can. Many tradesmen are now using sidecarriers, and I have seen several attractive combinations, which are splendid advertisements to the businesses of the owners. Evidently the work of *The Motor Cycle* has not been fruitless in this direction.

"If some live English firm would send an agent (a real businesslike one) to New Zealand to represent them specially and to keep large stocks of spare parts at low prices, I am sure our Parliament would recommend the directors of the firm for the V.C. or some such award.

"The Douglasses, though the price is £76 13s., are very popular; also J.A.P. engine twins for sidecar work, but the Indians run the J.A.P. engine machines close.

"I wish your paper, which is very popular here, every success."

MR. F. S. JALFREEZE, writing from Calcutta, India, says: "I have always had great difficulty in procuring spare parts, and in the future British manufacturers would do well to send out a plentiful supply at reasonable prices. I know this cannot be expected during the war, but afterwards British makers will be obliged to attend to this most important matter as thoroughly as the Yankees if they wish to increase their market."

Whilst the controversy respecting the £100 light car rages, luxurious sidecar outfits valued considerably in excess of this amount are popular in England. One such, costing £160, was described in *The Motor Cycle* of July 12th, and the power unit of this machine, a 7.9 h.p. Harley-Davidson, is illustrated above. It will be observed that the Remy lighting system is used in conjunction with a separate magneto.

### A TRIO OF ARIEL RIDERS.

**A**NOTHER interesting letter reaches us from F. C. North, the old Ariel rider. Since he last wrote he has been in most parts of the British line, and for the last two months has been spending a quiet time in a quarry some twenty miles from civilisation. The Boches occupied the spot last year. He tells us that he has not seen in that time either a civilian or a whole house, with the exception of an occasion when he had a day off, and went back behind the old line to find poor Fred Sangster's grave, in which search he was successful. North often meets Fred Langton, as he is in a brigade in his Division. The trio named will all be recognised as former Ariel riders. Langton's innings at the Front dates from August, 1914, and North runs him close for length of service.

### IMPROVING ROADS IN MACEDONIA.

**W**RITING from Salonica a despatch rider says: "My letters hitherto have dwelt upon the extremely rough roads in this part of the world; but if you saw some of the roads which have been made since the British Army landed here you would be astounded. Of course, very heavy traffic is constantly passing over them, and a lot of repairing is needed. What a pity it is there are not more roads like them, for after reasonably comfortable riding we suddenly strike a 'native' road, and get terribly shaken up. My friend had the misfortune to have his steering column break the other day. This is the third mishap in a month. Frames occasionally snap, and even the handle-bars break, so you can imagine the terrible state of the road surfaces. Of course, we think nothing of saddle springs and front fork springs snapping."

### MOTOR CYCLISTS IN CAPTURED ENEMY TERRITORY.

**M**EN of the motor cycle workshops at Dar-es-Salaam, G.E.A., have followed the discussion of flat twins in these columns. Sgt.-Mech. J. D. Mail writes: "Just a line or two from our part of the globe in appreciation of your splendid paper. While up country and out of touch with postal facilities it was sorely missed, but recently I have been able to get my copies regularly. As a rule I have quite a crowd waiting for me to hand over my copies for their perusal."

"We in the workshops here have been very interested in the discussion re flat twins. For myself, I think they are really marvellous engines, and do almost impossible things. One is surprised when

overhauling derelicts to discover that the interiors of the engines are invariably in first-class condition. Of course, most of the models here are only of the two-speed type, unfortunately; but fitted with an emergency gear it is the ideal machine for solo work. Of course, the Triumph and B.S.A. are grand machines in their class; but on these roads, where it is impossible to ride in some places, the handiness of the little flat twin is very noticeable.

### Are Magnetos Waterproof?

"One of the greatest troubles we have here is the magneto, many (so-called) waterproof magnetos being anything but such, and it is quite a common sight to see a despatch rider by the roadside toasting his armature and windings in his mess tin. Of course, you people will say drastic treatment, but I can assure you he finds it the only method on the road.

"Back wheels, rims, and spokes especially call for great improvement, also more efficient mudguarding. Most of the machines on the road are denuded of the last-mentioned appendages.

"I have been very interested in the performances of the A.B.C. engine, and have been in touch with a couple in my district (Pietermaritzburg, Natal) for two years or so, and have decided that

my next mount shall be a  $3\frac{1}{2}$  h.p. twin A.B.C., with all due respect to Mr. de Lissa.

"In our workshops here the lathe (a small Drummond), drilling machine, and emery wheel are driven by a  $2\frac{3}{4}$  h.p. Douglas through a countershaft gear box, and it does its work excellently, running very often for eight hour spells."

### POWER OF TWO AND FOUR-STROKES.

**W**HICH type of engine gives the greater b.h.p. — two-stroke or four-stroke? This simple question raised during officers' mess at a certain military camp subsequently led to heated arguments. Whilst the majority contended that the two-stroke would win—the double explosion largely attracted that section—the opinion in favour of four-strokes was really weighty. Since money was won and lost after the question had been put to the Editor of *The Motor Cycle* for decision, it would be of considerable interest if any engineer who has actually subjected both types of engines of similar sizes to brake horse-power tests would chronicle his experiences, supplemented by the figures obtained. Power is the only question involved.

The British Red Cross Society and the British Ambulance Committee have both sent out ambulances and men to the French Army. Mr. G. F. Haywood (on right), formerly on the staff of *The Motor Cycle*, was with No. 2 Section Sanitaire Anglaise of the B.A.C., and is now in the R.N.A.S. Both the riders are astride Rover motor cycles.

**The Motor Cycle of

## The High-grade British-built Magneto!

# B.L.I.C.

THE BRITISH LIGHTING & IGNITION CO. LTD.

The "B.L.I.C." Magneto is produced by an organisation with many years of practical experience in the manufacture of magnetos of the finest type.

The most careful scientific research into every detail, and the absolutely accurate standards of construction employed, have placed it in an unassailable position as the most perfect magneto yet produced.

**THE BRITISH LIGHTING & IGNITION Co., Ltd.**  
(Proprietors: VICKERS, LIMITED),  
204, TOTTENHAM COURT ROAD, LONDON, W.1.

## WHO IS THE YOUNGEST D.R.?

RECENTLY the question was asked as to who was the youngest despatch rider on active service, and the case of Motor Cyclist W. Norman Roughley, of Rochdale, was instanced.

Despatch Rider W. N. Roughley, R.E.

Young Roughley was but eighteen years and two months when he went out to France. He is depicted in the accompanying photograph astride his Douglas, and he looks very happy in his steel helmet.

□ □ □

## THE KING AND THE TANKS.

ONE of the most amusing and picturesque descriptions of the Tanks that has ever been penned was sent by the special correspondent of the *Times* on the occasion of the King's recent visit to the Front. We give this vivid word painting in full.

"The King and his party strolled across an open field with no sign of danger anywhere, except that close by on one side was a little patch of woodland. Suddenly the woodland began to quake and move as Birnam Wood never did. The bushes crunched and crackled, and the tree-tops swayed as if a herd of elephants were browsing within. Then one fair-sized tree began slowly to lean over towards the King, bent down till its crown rested on the ground, and then snapped. The undergrowth heaved and gave out strange rumblings, as of some huge monsters making great exertions, till, with a crash and amid an ecstasy of swaying greenery, out through the bushes came Leviathan.

"It was very horrifying to see as it came lurching and puffing out—first the hideous huge snout, and then the ponderous shoulder lifting through the bushes. Nor was it alone. Close beside was its brother—if possible, uglier and more grotesque—with hits of branches wreathed about its abominable head. Together the twin primordial monsters rolled out into the open, grunting and searching for something to destroy.

"A trench had been prepared for them—a nice deep trench—with stout wire before it, and dug-outs such as the Germans love to shelter in. The brutes saw it all, and, lurching horribly, they moved upon it. The stout wire bent down

like weeds before a garden roller on a path. They came to the trench and nosed along it, so that one could almost hear them snorting, 'Fee-fo-fum!' They were smelling blood; they cuddled down upon the trench and rolled the parapet flat; and it would have been bad for any Germans thereabouts. Then they attended to the dug-out, moved up to it curiously, and hesitated at it, dallied doubtfully with it for a while, then lay down upon it, and the dug-out opened out like a lily, and was a practicable dug-out no more. The deliberate intelligence and ponderous mercilessness of the great beasts were dreadful to see.

## The King in the Tanks.

"Then another Tank arrived—but a friendly Tank, this—and the King and Prince of Wales climbed in through the hole in the side and went for as fantastic a ride as ever a King had.

"Yet one more Tank gave a gymnastic display of ground and lofty tumbling. The King stood facing a steep bank almost as sheer as the side of a house. From the other side a Behemoth came lumbering up the slope to the bank's crest, and there it rested, peering down the abyss below. It seemed impossible that it could expect to come down; but while all the spectators held their breath, the gigantic thing slowly lowered its blunt nose into space, and then headlong it plunged.

"Why it did not roll over on its back only Tank experts know. For one moment it seemed as if it must, for the great bulk crashed against the ground and rocked right over on one side, to hang suspended for an instant, and then slowly swing back upon an even keel. The King ran up and met the young officer in command of the land ship as he climbed out and came ashore. The King asked him if he was hurt, and on receiving a laughing answer in the negative, insisted on all the crew of the Tank coming out, that he might look at them and talk to them. So the Iron Horse of Troy opened its side, and the whole crew came scrambling out, to stand to attention, breathless and smiling."

## WAR-WORN MOTOR CYCLES.

A FRENCH reader, residing at Boulogne-sur-Seine, writes to us concerning the offer by the British Red Cross Society of second-hand motor cycles used on the French front. He considers that it would be more economical to dispose of these machines in France, where, owing to the scarcity, motor cycles are commanding high prices. Personally, we look upon the suggestion as a sound one, since there is no dearth of second-hand machines in this country; and, moreover, the trouble of handling motor cycles on the cross-Channel trip would be avoided. We have communicated the suggestion to the British Red Cross Society, and the Director of the Motor Ambulance Dept. has been good enough to express his views. It appears that owing to the prohibitive duty that would be charged were the motor cycles sold in France, the course is impracticable.

□ □ □

## FOURTEEN MONTHS IN FRANCE.

WE recently had a letter from Cpl. C. T. Ringham, Despatch Rider R.E. Cpl. Ringham was for many years in charge of the new and second-hand motor bicycle department of the Service Co., Ltd. He has now been a despatch rider for fourteen months, and is with the British Expeditionary Force in France. He writes: "I am glad to see that *The Motor Cycle* is, if anything, more interesting than ever. It is certainly a link with old associations, and does not suffer through the war. I am riding a Triumph, and have nothing but praise for this make, which, as you know, I have had the pleasure of handling, among many other makes, for some years. You may take it that a three-speed gear and a hand-controlled clutch are necessities out here. For example, when going up to a brigade at night, with no lights, on a vile and narrow road, on which there are crawling ammunition lorries and restless mule teams, this system of control is a boon. The way the Triumph stands up to the work is marvellous."

Despatch riders attached to the Royal Flying Corps, all mounted on P. and M. motor cycles. The photograph was sent by the parents of Cpl. Thornton (fourth from left). Previous to the war Thornton rode an Enfield in several trials.

## TIME TO LIGHT LAMPS

SUMMER TIME.

" 30th	...	9.21 "
Aug 1st	...	9.18 "

### Petrol Consumption in U.S.A.

During the nine months of current fiscal year the United States exported approximately 290,000,000 gallons of motor spirit. Yet during that period she consumed three times the quantity.

### Petrol in the West.

Several of our readers propose to ride from London and the Midlands to the north coasts of Devon and Somerset, and would be glad to learn the experiences of others with regard to the difficulty or otherwise of purchasing petrol supplies *en route*.

### Heavy Hand Clutches.

Many riders, who complain of the stiffness of their handle-bar clutches have only themselves to thank for this state of affairs, in that the clutch springs are often tightened up a good deal harder than they need be. The tension need be no greater than just to avoid slip, which, if chronic, would spell short life for the clutch plates.

### Bedell's Ride.

Alan T. Bedell—who rode across the United States (3,296 miles) in 7 days 16 hours 16 minutes on a four-cylinder Henderson—as a precaution changed his tyres and chain after the first 554 miles, re-tyring again at Kansas City, this set lasting him the journey into New York. He experienced only one puncture during the ride. The only mechanical troubles were broken fuel pipes and front fork springs, and apart from new valve springs, a couple of chain changes, and tyre renewals, no replacements were made.

### Horse Racing and Motoring.

The Jockey Club, by their persistence, have been successful in securing the Government's permission to continue racing. Their plea has been that by racing only could horse breeding be kept at its former high level of excellence. Comparisons are odious, but one wonders whether the motor industry has not been too unselfish in refraining from fighting the restriction that has been placed upon it. There is no questioning the fact that the innumerable Government orders have tended to create an unreasonable public feeling against motoring by private individuals, no matter how justifiable may be the reason for using either a motor cycle or car.

THE HOTTEST PART OF AN ENGINE. ENGINE AND GEAR BOX AS A UNIT. OVERSEAS SECTION.

### Our Importation of Petrol.

Our petrol imports for the first six months of 1917 were nearly 69,000,000 gallons. This is a falling off of 1,000,000 gallons compared with the quantity imported during the first six months of 1916, but an increase of 6,000,000 gallons over the same period in 1915, and 9,000,000 gallons over a similar period in 1914.

### The Late William Heaton.

The funeral of William Heaton, of Atherton, near Manchester, whose sad death we recorded in our last issue, took place last week at the Atherton Cemetery. Among the mourners were: G. Cowley, W. Mason, C. E. Kettle, Jack Stevens, J. Stevens, sen., and O. Wade, representing the Liverpool Motor Club, Manchester Motor Club, North-Western Automobile Association, Stockport and District Motor Club, Wolverhampton Motor Cycle Club, etc. Amongst the many beautiful floral tributes were those from A. J. Stevens, Ltd., A. J. Stevens's employees, Percy Butler, Colmore Depot, G. Cowley (Manchester), J. Chapman (Wolverhampton), fellow motorists at Tyldesley, F. Lord (Tyldesley), Liverpool Motor Club, W. Mason (Walsall), Manchester Motor Club, Stockport and District Motor Club, A. J. Stevens (family), Jack Stevens, Wade and Smyth (Liverpool), and Wolverhampton Motor Cycle Club.

### Mechanics for the U.S.A. Army.

Mechanics offering their services to the U.S.A. War Department are entered as enlisted men at 37s. 6d. per week.

### Pillion Riding.

Though, as our readers well know, we have not given our approval to pillion riding in the past, it cannot be denied that it is an economical form of motoring; moreover, given the proper passenger, less agreeable form of economy might be experienced.

### Motor Cycles at Evesham.

Motor cycles appear to be numerous in the wide vale of Evesham, and it is seldom we pass through the picturesque old town without observing several machines stacked up by the sidewalks. It would appear indeed that some of the citizens use the public roads as garages.

### Flat Twins and Speed.

The modern overhead valve flat twin of 350-400 c.c. is probably the fastest machine on the road for moderately flat country, but on mountainous roads it is hard put to it to hold its own against a really good  $3\frac{1}{2}$  h.p. single or touring twin. More gear changing is necessary, but one advantage of the highly efficient flat twin is that it is extremely fast on its middle gear and does not overheat. A four-speed gear is almost essential for this coming type of solo mount.

### ON THE MALVERN HILLS.

Instead of the usual great pre-war crowd of cars and motor cycles usually found in front of the British Camp Hotel near Malvern on any fine Sunday, a bare half-dozen or so is about the usual number found there in these days. It is, of course, a state of affairs to be expected, but what a contrast!

**The National Relief Funds.**

At the week-end the principal war funds stood as follow:

The National Relief Fund (distributed £3,651,632) .. ..	£6,213,796	0	0
British Red Cross Fund .. ..	£7,101,106	4	8
Tobacco Fund .. ..	£134,068	2	1

**American Tourists.**

The American tourist is not yet extinct. Recently, in North Devon, we met a party of four Americans, who had between them two Douglasses, a baby Triumph, and 18 h.p. Minerva car, all of which were used on daily joy rides. How and where did they get their petrol?

**Fuel from Peat.**

A committee has been appointed by the Fuel Research Board in order to ascertain the utilisation of Irish peat deposits. We know that motor fuel can be produced from peat, but details are not to hand concerning the exact investigations of this special board. There is no questioning the fact that millions of gallons of fuel could be obtained by utilising these great peat deposits; but whether it would be a commercial success is another question.

**The Utility Car.**

Even the most conservative must admit that the Ford car is a marvellous proposition. This was brought home to us when recently visiting South Wales, as we had an opportunity of observing the neglect and hard usage to which many of these vehicles are subjected in the hands of stewards and farmers. From tractor to milk float the Ford figures, but if the possibilities of the commercial side-carrier were more fully realised, it would no longer hold the lion's share.

**Standardisation.**

We have already stated that the motor cycle manufacturers in the States are considering the standardisation of parts and fittings. It is possible that certain parts, for the use on several makes of motor cycles destined for France, may be produced by one firm; whilst other parts, also intended for fitting to various makes, will be turned out by another factory. If this idea be carried out the maximum production will be attained very quickly.

**Humour—Intentional and Otherwise.**

We read last week that it is a good plan when buying petrol to weigh each can on a spring balance, provided, of course, that one carries such an ornament on one's watch chain. The weight of petrol is stated, but as not even an approximate weight is given for the can, we suggest that a better plan would be to remove the petrol from the can and weigh it by itself on the balance, afterwards returning it to the can for convenience of transport.

From the same source we learn that "a motorist has been fined £10, or six weeks, for driving without a licence at West Ham Police Court." How foolish! If one must drive without a licence, it is wiser not to do it at a police court. Lastly, we are informed, still from the same page, that the moon, two days old, rises about one hour and twenty minutes before sunset. It must therefore rise in the West. We presume it adopts this unusual procedure because there is a war on.

**Plugs for Oily Engines.**

A correspondent asks us which is the best type of plug for a highly-efficient flat twin the back cylinder of which is normally aswirl with oil. We have experienced the same trouble ourselves, and have found that the only way out of it is to strike the happy medium between a wet plug and a starved engine.

**A Big Demand.**

With the flat twin a certain amount of oil, drained from the rings while the engine stands, is certain to find its way into the combustion head, and since this type of engine is destined to become popular, big profits await the firm that produces a truly oil-proof type of plug.

**And Special Constables Too!**

Three special constables, out for a trip in a motor cycle and sidecar with two guns, were each fined £4 4s. at the Nottingham County Bench recently. Early on a Sunday morning a policeman heard shots fired from the direction in which they were travelling. In the sidecar were a pheasant, partridge, and three rabbits, all freshly killed, as well as the two guns. The magistrates, in fining the men, ordered the guns to be forfeited.

**Memorial to the late Rear-Admiral Arbuthnot.**

A tablet was unveiled in St. Giles's Cathedral, Edinburgh, on Saturday afternoon last, in memory of the late Rear-Admiral Sir Robert K. Arbuthnot, who was lost in the Battle of Jutland. Lord Inverclyde (a relative) presented the tablet, which occupies a prominent place on one of the pillars supporting the tower near the pulpit. Those present included Admiral F. T. Hamilton, Admiral Spartin, and Lt.-General Sir J. S. Ewart, Commanding in Scotland. The ceremony of unveiling was performed by Admiral Hamilton, who paid a warm tribute to the bravery and seamanship displayed in the fight by Sir Robert Arbuthnot and the men who fell with him.

**Our Highways of the Future.**

After the war an absorbing topic with motor cyclists will be improvement of the roads, and information concerning modern ideas in road construction and administration is particularly interesting, in view of present-day road conditions. The pamphlet of the report on concrete roads, issued at the instance of the Roads Improvement Association (Incorporated), 15, Dartmouth Street, Westminster, S.W.1, shows that one association at least is alive to modern tendencies. This informative brochure at the outset contrasts the "English" engineer and British methods with the American, and says that the English engineer's caution should not be a sufficient reason for him to show timidity where progress can, and should, be made, and suggests that the use of concrete as a road material might be given a better chance in the future than it has received in the past. Reports as to the wear of existing concrete roads in England and Scotland show that they have not all been successes, and that, in spite of their unquestioned success in America, unless scientifically built failure can easily occur.

**American D.R.'s.**

The amateur and professional motor cycle tract riders in the various towns of the United States are busy answering the call to the Colours, and no doubt many fine riders will be among the drafts of D.R.'s soon to reach France. They will find the "roads" at the back of the line a different proposition from the saucer tracts to which they have been accustomed.

**AVERAGE PRICES.**

WE give below the prices of second-hand machines offered for sale in the last issue of *The Motor Cycle*, and in the adjoining column the average prices based upon the latest figures available. Thus the general trend of the market is visible at a glance, though in the first column many blanks inevitably occur. This is due to an insufficient number of one model on which to base an average. The word "combination" indicates a sidecar outfit as supplied by the makers, while "sidecar" implies that the fitting has been carried out by the owner.

## THE MOTOR CYCLE IN JAPAN.

Spring Frames, Large Wheels, and Large Tyres are desirable features on an Overseas Motor Cycle from the point of view of the Writer.

(1) The military road winds up a range of mountains to a height of 3,000 feet above the sea level.

(2) A typical native house belonging to "well-to-do" Japanese people.

(3) One of the wooden toll bridges referred to in the article.

**E**VEN as recently as three years ago old creaks of anything from 1 h.p. to  $2\frac{3}{4}$  h.p., which had probably seen years of hard service and suffered in silence words of abuse from their owners before ultimately finding themselves in this land of sunshine and flowers and earthquakes, were being sold in Tokyo as new machines, disguised in glaring coats of new paint. But motor cyclists, be they Europeans or Asiatics, are nothing if not enthusiasts, and now these poor old stagers have been relegated to the scrap heap and replaced by modern machines. Every reputed make is represented; but it cannot be said that this king of sports has yet taken a hold of the enterprising Japanese. There is a band of enthusiastic European and American motor cyclists in Tokyo, of whom the writer, who graduated from his novitiate in England in the good old days of the front wheel driven Werner and Minerva-engined mounts, is one. It is hoped that a club will soon be formed. There exists already in Kobe a motor cycle club, which, under the presidency of a keen American, held recently a hill-climbing competition, the first event of its kind in Japan. The event was won by a  $3\frac{1}{2}$  h.p. Bradbury, the formula adopted being the one published by *The Motor Cycle*, viz.:

Weight

Time<sup>2</sup> × Capacity

Twins, less 10% capacity.

### Japanese Roads.

The roads in Japan are generally comparatively good, and in places excellent. Of course, owing to the mountainous nature of the country, a road which one day is ideal, may on the next, after a heavy rainfall, become impassable. Then, owing to the extremely simple and crude system of road mending, which consists in dumping a generous layer of pebbles (locally known as "petrified kidneys") brought from the river beds and leaving it to the traffic to "work" them in, woe to the unwary cyclist who strikes such patches of a newly repaired road! Dry skidding on these stones is not pleasant. The absence of bridges, too, in the interior makes distant touring exciting and strenuous work, if not altogether impracticable at certain times of the year. Most wooden bridges spanning the rivers, which during the dry season are mere streams, but which swell into mighty rivers after a few days of torrential rain, are swept away and not replaced for months. There are also temporary toll bridges put up by villagers, who, with commendable foresight, take the precaution to pull them down when a heavy rainfall is anticipated and re-erect them when the danger

**Motor Cycling in Japan.—**

is over. The illustrations give a fair idea of a bridge of this description. It is on the fine military roads that the motorist may, in the absence of police traps, scorch to his heart's content. These roads are well engineered and maintained in good repair.

Artificial manuring has not yet been adopted by the Japanese farmer. He still adheres to the primitive methods of his forefathers, which appeal strongly to the olfactory organs of the European. Collectors of night soil from the neighbouring villages come in daily to the city, and to avoid the carts with their odoriferous loads as they wend their way homewards is not particularly in the absence of any rules of the road—an easy or pleasant task.

Few side walks, if any, exist outside the limits of the larger towns. The middle of the road is therefore the favourite playground of children and chickens, and the toot-toot of a motor horn or the crackle from the exhaust of a healthy single not only scatters them but brings fresh consignments from every lane and backyard.

I notice in your columns that much controversy exists in regard to machines for Colonial use. I do

not know what Colonial conditions are like; but, speaking from experience of the vile roads in some parts of Japan, I consider a sprung frame, large wheels, and, say, 5in. to 6in. road clearance, a *sine qua non* for comfortable and safe travelling. I ride a popular American heavyweight twin with sprung frame and 28in. wheels fitted with 3in. tyres, and my companions, who ride standard British productions, often complain that they find it difficult to keep pace

with me on the terrible pot-hole roads, whereas I find little discomfort, my machine ticking gently over on the pilot jet at about 20 m.p.h. and riding over the holes and bumps without undue buck-jumping, the spring frame and large wheels and tyres, coupled with the heavy weight, enabling the machine to hug the ground and insulate the rider from the shocks. It is time the British makers realised the

necessity of building machines specially to meet the requirements of Colonists if they wish to check the American invasion. The Japanese favour British goods on account of their high quality; but this point is not everything, there are many other essential features to consider.

J.D.M.

A temporary toll bridge erected by the natives in place of the ordinary bridge swept away by torrential rains.

## A GREAT RIDE.

Transcontinental Trip of 3,296 Miles. "Ixon" on Four-cylinders.

ONE of the finest performances on a motor cycle has just been accomplished by an American rider, Alan T. Bedell, who, mounted upon a four-cylinder Henderson, rode from Los Angeles to New York in 7 days 16 hrs. 16 mins. From the Pacific to the Atlantic coasts is 3,296 miles, and the trip is a favourite form of "record," but Bedell's wonderful time beats all previous one-man attempts in any sort of vehicle.

Commenting upon the remarkable performance, "Ixon" writes: "The many readers who believe in the ultimate triumph of the four-cylinder principle on tourist machines will doubtless take unction to their souls as they read of the latest Henderson stunt. Mr. Alan T. Bedell has just ridden a 1917 model from the Pacific (Los Angeles) to the Atlantic (New York), a distance of 3,296 miles in 7 days 16 hrs. 16 mins., an average of 426 miles a day. Some of us have seen British riders after a six day stunt of 400 miles a day for six days on selected British roads, which are—or

Alan T. Bedell.

should I say 'were'?—appreciably better than American roads are on the average, and we do not envy Bedell. The last British rider who put up a ride of this type was in a fairly pitiable condition at the finish, and though I do not know the American coast to coast route, I suppose the job is far tougher than our own six-day records, and that without making any allowance for the extra forty hours in the saddle. To name one point only. Bedell must have ridden slowly for a large part of the distance, and, consequently, he must have spent more hours in the saddle. But the selection of a four-cylinder, with its multiplication of parts and of possibilities of small derangements, shows that the modern Henderson is some bicycle. I do not recollect a previous example of a four-cylinder doing anything really good in long distance work of a public character. If four cylinders are going to put up shows of this nature, we shall have to consider them more seriously when we plan our post-war de luxe models. I do not mind confessing that if I were set to tackle a job of this kind I should certainly select a single-cylinder for the sake of its substantial simplicity. But Bedell actually selects a four-cylinder, and then proceeds to knock nearly four days off the best motor cycle times."

## THE RED CROSS DRAW.

£3,200 received in Ticket Money. A Chat with the Khaki Winner.

**W**E were able to announce in our last issue the names and addresses of the holders of the winning numbers in the Red Cross draw, organised by the Newcastle (Staffs) British Red Cross Society.

We have received a very appreciative letter from the chairman of the Draw Committee, Councillor Sidney W. Carryer, who mentions that our readers subscribed about £400 worth of tickets. He goes on: "Miss Phyllis Carryer received thousands of very charming letters from your readers both at home and abroad. On behalf of the committee I wish to offer you our very best thanks for the splendid editorial references to the draw, the value of which have been fully appreciated by us."<sup>22</sup>

In all, twelve thousand letters were received in connection with the Newcastle (Staffs) Red Cross raffle, the total sum contributed for tickets being £3,200.

A charming little letter has been received from Miss Phyllis Carryer, who assisted her father in connection with the dozens of letters received each day, enclosing remittance for tickets. Its contents are addressed to our readers.

July 19th, 1917.

Dear Mr. Editor,—So many thousands of your readers have sent me such lovely letters wishing success to our Red Cross raffle for the Triumph motor cycle and the pony, and sent such a lot of money (about £400) for tickets, I want you through *The Motor Cycle* to thank them all, as there are far too many for me to write to myself, because I am only eight, and so many of them are soldiers or sailors they are sure to want a letter, so if you put it in your paper they will all see it. Also I want to thank you for your great kindness in helping us so much.

With best wishes to yourself and to all your readers,

With love from

Miss Phyllis Carryer.

PHYLLIS.

As soon as we heard that the  $2\frac{1}{4}$  h.p. Triumph motor bicycle which had been raffled by the British Red Cross Society's branch at Newcastle-under-Lyme had been won by Mr. A. F. Jakins, we hastened to call upon him, and found him at Durham House, Crouch Hill, London, N., an auxiliary hospital of which he is an inmate. It is interesting to record that Gunner Jakins joined the "Tanks" through *The Motor Cycle* last year, went through his training, and was in the "push" on September 15th, 1916, when the "Tanks" were first employed. They had to go into action in terrible weather and over surfaces which had never been anticipated in this country, yet his Tank, which has been many times in action, got through splendidly and was never stopped on any occasion. Unfortunately, the first time Gunner Jakins's Tank went over the top he was looking through a sight-hole when a bullet struck the edge, several portions of the splinter entering his face just below the lower eyelid of the left eye. However, he soon recovered from his wound and went into action again, and is now home suffering from a nervous breakdown and deafness.

He is an old motor cyclist, and has had a good deal of experience, as he has had about ten different machines. After his training at Bisley he was taken to a secret camp, when he learnt all about the monster with which he had to deal, and while at this place he rode a  $3\frac{1}{2}$  h.p. Rover, which he found to be a great blessing. That was in the days when petrol was plentiful. He has also ridden Douglas, Norton, Indian, Kerry-Abingdon, and Levis motor cycles.

Asked whether he had yet received delivery of his prize, Gunner Jakins replied that he had not, as he did not intend riding just at present, and did not think a motor bicycle would be much use to him. Moreover, his preference was for a  $3\frac{1}{2}$  h.p. T.T. model, and not a low-powered lightweight. Consequently he prefers to receive the prize in cash rather than kind.

## MOTOR CYCLE VOLUNTEERS.

Organisation of the Lancashire Forces.

**T**HERE was a time some two years ago when motor volunteers were looked upon by the majority as shirkers because many were young men who might well have been serving their country. This state of things no longer exists. The country has now the right to call upon all those of military age to serve in the Army, and if any man is still to be found in a civilian capacity it is because the authorities consider that he is better employed in that way. Then again, many volunteers (motor cyclists and others), are men over military age and consequently barred from service in the regular forces, though they may be active and energetic men. The fact that the volunteers are now recognised by Government and organised for home defence gives men of this most useful class an opportunity of rendering themselves efficient defenders of their native land.

Some few weeks ago we published an account of the Lancashire Volunteer meeting at Blackpool. The Lancashire Volunteers are now divided into three groups with Manchester, Liverpool, and Blackburn as centres, and are under the command of the County Commandant. Col. Smith has now been gazetted temporary colonel, Major Rigby, the county adjutant, temporary major, and the adjutant of No. 1 group has been gazetted captain. The motor cyclists are maintained at a strength of sixty, notwithstanding the calls of the Army. The men are just settling down after the reorganisation caused by the official recognition and necessary change from the old method of working to the War Office requirements. Each motor cycle section now has a sergeant, corporal, and lance-corporal, but there is no allowance for specialist motor cycle officers.

# THE Critic

## Fireside Chats on Motor Cycle Problems

### Which gives the Higher B.H.P. — Two or Four-stroke?

"THIS," said the D.R., "was one of the stock arguments used to beguile away the hours by a certain little group of D.R.'s when the eternal monotony of trench warfare first began." "We never quite settled the question," added the Discharged Soldier, knocking out his pipe. "Some of the boys backed the four-stroke—others the two. Among us was a Scott T.T. rider, who used the Scott as a fearsome weapon, and we left the question as we found it, still unsettled." "Which did you back?" queried the Journalist.

The D.R. was cautious. He said that his views on the subject were rather flexible, but that, on the whole, he backed the two-stroke.

"Then you were wrong," bluntly stated the Manufacturer. "An R.F.C. officer asked me the same question a week or two ago, and I told him without hesitation that the four was the more powerful. I took that as an admitted fact."

"Why?" queried the D.R. "Because everything points towards it. Take public competitions, for instance. Has a two-stroke of the same c.c. achieved the results that many of the fours have achieved? More than one 2½ h.p. four-stroke has done 60 m.p.h. at Brooklands."

#### Two-strokes and the T.T.

"I admit all that," stated the D.R. "I admit that a four-stroke can be built fairly to 'eat up' a two-stroke of the same c.c. It can be fitted with overhead valves, for instance, and specially designed and tuned for racing, whereas the designer and tuner of the two-stroke has a very limited scope. He is dealing with an engine which is more of a compromise, and he is up against certain difficulties which only time will remove. He cannot improve his scavenging beyond a certain point, for instance, or draw a gigantic gulp into his small engine—things that are comparatively easy to perform in the case of the 'four.' But my point is this—you take a dozen two-strokes and a dozen four-strokes off the road, and I'll bet you the two-strokes will knock the four-strokes clean off the map. Please lend me a match."

The Manufacturer, fumbling absently in his pocket, produced a match-box and handed it over, remarking, "You contend that the four-stroke scores simply because it can be built and designed for speed to an extent which is impossible in the case of the two-stroke. Is that so?"

The D.R. agreed rather shakily—that it was.

"Then," announced the Manufacturer, "your argument is knocked absolutely

sideways by the practical demonstration afforded by the Scott, to which you have already alluded. Did not the Scott win the T.T. on two occasions and establish fastest lap on another? Was not that the result of a specially designed engine and of special tuning? The four-strokes were given the same attention, yet they were beaten by the two-strokes. Was not that so?"

"It was," agreed the Novice. "Which seems rather to defeat your own argument that a four-stroke is more powerful than a two-stroke."

"No, no!" protested the Manufacturer. "I do not under-estimate the value of the T.T., but everyone knows that it was won not necessarily by the best engine, but by the best combination of luck, rider, engine, and machine. I have merely used the Scott to show to the D.R. that the scope of the designer is no more limited in the case of a two-stroke than in the case of a four-stroke. And everyone knows that it was not only the excellent engine, but the marvellous controllability of the Scott machine, coupled with marvellous riding, which won the T.T."

#### Touring and Trials.

This seemed very reasonable and sensible, and the D.R. had nothing pressingly urgent to say, so that he was glad when the Journalist chipped in.

"I agree with the D.R. that in freak engines the four-stroke permits more scope than the two," he said. "Because one ingenious designer of a two happens to have carried off the T.T. seems to me to signify nothing. Have not four-strokes won the T.T.? But, talking about freak engines—"

"What about the 85×60 mm. J.A.P.?" the Manufacturer interposed for him. "The machine that Harry Martin has used for years. I tell you, the four-stroke wins hands down. Compared with a 'fluffy' two-stroke, the four-stroke has 'kick' and 'snap' about it."

"But the two-stroke is the more powerful in touring practice," put in the Novice. "That is the only thing that matters to me, and men of my stamp compose 90% of the purchasing public."

The D.R. agreed that the Novice certainly was an ordinary—very ordinary—juggins, and that therefore his opinion ought to carry some weight. "It is for such blithering idiots," announced the D.R., rudely, "that motor cycles are designed. The world is composed of them, and the manufacturer has to cater for the world—not for the individual."

"Look here," said the Manufacturer, "you are all trying to evade the point of public competition, which is the only

thing that carries any weight. You can talk about the two-stroke being better than the four in the hands of the private owner, but where is your convincing proof? One of the most striking examples of the superiority of the four-stroke was afforded by the last A.C.U. Six Days Trials, when Neville Hall rode a 2 h.p. O.K. fitted with an Albion three-speed countershaft gear."

#### Modern Progress.

"Hm," scoffed the D.R. "I used to have a 2½ h.p. four-stroke, which I used for blinding into Scotland—120 miles—to see my best girl. During the week-end I used to keep the girl busy holding little oily bits, while I took out the valves, etc., for grinding, so that I could get home on Monday and avoid the sack. The girl got sick of the job, but if I had possessed in those days a modern two-stroke of the same c.c., then—no telling what might have happened."

"Just so," agreed the Manufacturer, "and if you had possessed a modern four-stroke of the same c.c., the Celtic accent might flavour the conversation of your children. I defy you, or any other man, to burn out the valves of a modern four-stroke in 120 miles. I bet the modern four-stroke lightweight of that power would tire you to a standstill ere you affected its polish! We know a little bit more about metallurgy now, and modern valves will maintain their condition for an indefinable period."

"Where is your two-stroke that has held its end up against the A.J.S. lightweight?" queried the Journalist.

"Have not yet found it," admitted the D.R. "In the 1913 trials I was riding a 3½ h.p. single, renowned for its unfailing engine, and more than once that year the little A.J.S. left me standing. It was almost like a death blow when Wolverhampton gave up making it, and the same applies to the little Sunbeam. Still, I hold out that the two-stroke is the better engine in the hands of the ordinary rider. I have never tried a small four that could hold a candle to my last two-stroke, a Velocette, as a no-trouble economy mount."

Thereafter argument pivoted round the central point. The two-stroke, owing to its present inefficient oiling, etc., required decarbonising at appallingly close intervals. The four-stroke had valves, valve clutch, and valve adjustment, which required mechanical judgment. Finally, it was decided that undoubtedly the two-stroke would triumph, but that, as concerned the argument, the four-stroke is, to-day, more powerful on the b.h.p. test than the two.

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

### TWO-STROKE PISTON RINGS.

Sir,—If "Piston Rings" will try the use of Oildag in his Junior Triumph I am sure that he will be pleased with the results.

I have used it on three different makes of two-strokes, and have yet to experience a "stuck-up" top ring.

The rings on the piston of my last  $2\frac{1}{2}$  h.p. Villiers were beautifully free and bright after 2,000 miles running, and had never been touched, although the other parts of the engine had been decarbonised three times in that distance.

For some reason or other I find that Oildag is of no use if mixed with Wakefield Castrol. SAFRICAN.  
Colne.

### PETROL PERMITS.

Sir,—There seems to be great scarcity of petrol, when applications are made for purchasing permits, to some motorists. I say "some" advisedly, as in this district I know of people who can run about to their hearts' content, and on pleasure trips at that. No doubt they are connected with firms doing "munition work," but surely it is time to put an end to their supplies when even any of the petrol is used to motor around the wives, families, and friends of these. They may also get petrol at less than "full duty"; I do not know, but if any difference is to be made in the duty charged it should surely be full duty to those who are making money out of its use! To apply for petrol for business, and use it, or any of it, for other running, is a low enough thing, and people who do this have simply no decency. But they should not be allowed to misuse this privilege, and it is time—high time—action should be taken against them by the petrol authorities. I can name several who are pleasure motoring regularly.

Surely something could be done if complaint were made in the proper quarter. WISHAW.  
WILLING TO HELP.

### INVERTED CONTROL LEVERS.

Sir,—I wonder if the anatomical aspect of the vexed question, "Inverted control levers," has occurred to any of your readers who favour this form of valve lifter and front brake control? Take either of these two levers and work it several times until the hand becomes fatigued, and then consider where the fatigue is felt the most. With the inverted lever the hard work of pulling it up falls on the weakest portion of the operating hand, namely, the third and fourth fingers, whilst the strong portion of the hand—the thumb and first two fingers—have an easy time.

In consequence, the inverted is a more tiring form of lever to work, and is not so conducive to delicacy of control. Anyone who doubts this can experiment with his front wheel brake for delicacy of control, on a stretch of slightly greasy sets. My present mount is afflicted with a pair of these inverted levers, and, apart from their utter inaccessibility, their discomfort is such that never again will a machine of mine be equipped with them. Perhaps when their devotees use them for their h.b.c. clutch operation a realisation of their inherent defects will come to them. The entire contour of the normal type Bowden lever gives the complex muscle system of the hand a correctly graduated load, an eminently desirable attribute.

Finally, the riders who require lever hooks on the end of their handle-bars to anchor themselves to their machines should revert to pedestrianism or travel by train. My congratulations to "Chinook" for his castigation of the inverted type. A. LINDSAY (Capt. R.A.M.C.)

B.E.F.

### SINGLE V. TWIN-CYLINDER ENGINES.

Sir,—As a reader of *The Motor Cycle* since the appearance of its first number, and as a rider of various makes of motor cycles since 1902, will you let me poke my finger in the "pie" with regard to the absorbing topic of "singles v. flat twins"?

Well, until the autumn of 1915 I had never had any real experience of "flat twins," but after joining the M.T. and coming out here, with thirteen flat twins, one of which was of the 4 h.p. type, I have gained much useful knowledge, especially from a Colonial's point of view. For thirteen months on the Somme front, on roads that at many times defy description, nothing could produce a more severe trial for any type of machine, and my opinion now is, that a small flat twin on these roads will, with care, last a year and run about 9,000 miles before it requires practically entirely renewing; the reason for this being that  $2\frac{1}{2}$  h.p. is not sufficient power, and 50% of the 9,000 miles is done on low gear, and this, combined with mud and dust, is sufficient to wear a high revolving engine out after a comparatively short life. Then, in consequence of much low gear work and high revolving, we get a considerable amount of magneto and plug trouble. The single-cylinder turning over at half the speed lasts, therefore, quite twice as long, and with less attention.

Now, as to engine balance, there is no doubt that the flat twin scores at high speeds on good roads; but out here engine vibration is quite drowned by the road vibration, and under these conditions my experience is that the heavier machine is infinitely more comfortable to ride, for its weight and better springing keep it to the road, while the little light machine is tossing about like a rowboat on a choppy sea, which results in many cases in broken front springs or broken frames. I personally have had three frames break under me, and I scale only 10 stone.

For the last month or so I have once more been riding a good old  $3\frac{1}{2}$  h.p. single that has seen a year and a half's work out here, and the engine seems as good as ever and the frame is still sound, in spite of the fact that the machine used to be ridden by an ex-trade rider, who rode fast and furiously, besides having done a turn up at the battery, where it had been used as a "hack" by R.G.A. men and officers. Therefore, until something much better in the way of flat twins comes along I stick to the  $3\frac{1}{2}$  h.p. single.

One more comment, and that is that, owing to so much low gear work on the small flat twin, the petrol consumption out here in any case is greater than on a single  $3\frac{1}{2}$  h.p., for obvious reasons.

I said that when my company came out here just over a year ago we brought thirteen flat twins with us. Out of these we have two left—one a  $2\frac{1}{2}$  h.p., the other a 4 h.p. model. All the rest have been evacuated.

I may say that I have nothing to do with the motor trade, and therefore have no "axe to grind."

B.E.F.

ROAD OFFICER.

### AVERAGE SPEEDS.

Sir,—I do not wish to be unduly pedantic, but, in the interests of accuracy, I should like to point out that the contributor of the article on the Blackburne engine in your issue of last week is guilty of an error.

Speaking of the efficacy of flywheels, he says: "20 lb. at a 3in. radius being equivalent to 10 lb. and a radius of 6in. so far as torque is concerned."

This is wrong. The efficacy of a flywheel depends on its "moment of inertia," which is equal to the product of its mass and the square of its radius of gyration, which

latter may conveniently be described as the "mean effective radius" of its mass distribution. Thus 10 lb. at 6in. radius is four times as effective as 10 lb. at 3in. radius, or twice as effective as 20 lb. at 3in. radius, and not equivalent thereto.

Again, as a lover of accuracy, let me thank you for the very intelligent remarks of "The Critics" on average speeds. Most men are liars in this respect, and I well know that to average anything over thirty means very hard riding indeed, and even the thirty mark needs some reaching. But I have done forty-five on a T.T. Douglas for a short distance after much tuning, but it is not common.

W. WHATELY SMITH.

Sir,—“The Critics” in your issue of July 19th make me wonder if the individuals mentioned have ever tried the effect of a little attention to the mechanical details of their machines when making average speed tests.

I agree with them that the majority of  $3\frac{1}{2}$  h.p. machines in use will not do 45 m.p.h., but that is the fault of the riders and not of the machines. Some time ago I made a trip from a place called Arneke to St. Omer (France) on a  $2\frac{3}{4}$  h.p. machine, timed with a stop-watch, and the distance (twenty-three and threequarter miles) measured off an Army map, the average speed being 47.85 m.p.h. At the end of the run, without any attention whatever to the machine, a kilometre was covered in 42s. (52.3 m.p.h.) This on a standard machine tuned as well as was possible for a Div. Sig. Co. D.R.

ARMIDUG.

Lewisham.

[Our correspondent has missed the point of the discussion to which he alludes. This was intended to show that the high average speeds over fair distances—say, London to Exeter at 45 m.p.h., sometimes claimed—were impossible. It was not suggested that a well-tuned machine was not capable of a high speed over a short distance on a good road. A Douglas has covered a kilometre and mile at speeds of over 72½ and 70 m.p.h. respectively, but an average of 45 m.p.h. for a considerable distance over most roads is a crime.—ED.]

#### CURIOUS FACTS.

Sir,—Under this paragraph heading in “The Critics,” July 12th issue, the Journalist says: “Let me tell you one or two facts . . . that may surprise you. A car is more economical for the weight it carries than a motor cycle . . . Why? Because a motor cycle is over-engineered and does not make the best of its engine.”

Although the first italicised statement may be taken, generally speaking, as correct, I submit that the answer to the query “Why?” is absolutely wide of the mark.

Comparing the performance of a motor cycle with that of a car. Given loaded weight motor cycle=3 cwt. and m.p.g.=100; given loaded weight motor car=25 cwt. and m.p.g.=20. Then performance of motor cycle=15 ton miles per gallon and performance of motor car=25 ton miles.

This bears out the statement that the car is more economical for the weight it carries.

Let us, however, examine further the relative performances of the motor cycle and the car. In each case the total external load of the engine is made up of (1) weight moving, (2) overcoming air resistance. Say windage area of motor cycle= $4\frac{1}{2}$  sq. feet and windage area of motor car =11 sq. feet. The engine of the motor cycle propels the vehicle against a certain air resistance, due to area ( $4\frac{1}{2}$  sq. feet) exposed, for 100 miles, in addition to drawing 3 cwt.—all for the expenditure of one gallon of petrol.

The performance of the motor cycle on the air resistance account may be expressed as  $4\frac{1}{2} \times 100 = 450$  units per gallon. Similarly the car performance (11 sq. feet windage 20 m.p.g.) may be expressed as  $11 \times 20 = 220$  units per gallon.

Thus the total performances of the two can be written: Motor cycle (15 ton miles+450 unit air resistance miles) per gallon; motor car (25 ton miles+220 unit air resistance miles) per gallon.

It is not necessary here to enter into the very involved process of reducing “ton miles” and “unit air resistance miles” to a common value; it is sufficient to state that any deficiency of the motor cycle in weight carrying is made up for by an overplus in overcoming air resistance, and that the relative total performances of the motor cycle and car per gallon of fuel consumed are practically identical.

The fallacy of the statement that the motor cycle is over-engineered is therefore easily seen from the above. Perhaps the fact may be emphasised by the following. In the above cases suppose motor cycle to be  $3\frac{1}{2}$  h.p. and motor car to be 20 h.p., then windage area of motor cycle= $4\frac{1}{2} = 1.2$  sq. foot per horse-power, and windage area of motor car= $11 = .55$  sq. foot per horse-power. Suppose the horse-power of motor cycle is increased to 8.18 h.p., then the windage area exposed= $4\frac{1}{2} = .55$  sq. foot per horse-power—the same as in the case of the car.

Now if the motor cycle were loaded up to 10 cwt. we should certainly expect it to run 50 miles per gallon, in view of the performances of the many light cars about. This would bring its performance,  $\frac{1}{2}$  ton, distance 50 miles, to 25 ton miles per gallon, i.e., same as the car.

We therefore come to the conclusion that, taking into consideration its windage area, the motor cycle for weight drawing purposes is under-engineered as compared with the car.

Baldon, Yorks.

#### PETROL FILTERS AND DIVIDED TANKS.

Sir,—I saw in one of the motor journals some few weeks ago that, according to Capt. B. C. Hucks, “dirt in the petrol” was a far too common cause of engine stoppage whilst pilots were up in the air, particularly in trying new machines.

A pilot may not be able to see that his petrol is strained when his tank is filled; but if he had a 4in. circular filter fitted in an accessible position, with a detachable screwed top, he could quickly satisfy himself whether that was clean and capable of straining all the petrol in his tank.

There is another danger which should be guarded against, if it is not already done: Aeroplanes in action frequently have their tanks punctured by shrapnel or machine gun fire. Petrol tanks could be constructed in separate compartments, with the dividing wall forming a complete separation, and a filler cap to each compartment; or the dividing wall could be brought to within an inch or two of the top of the tank, with a common filler cap for all compartments. A pipe could then be taken from each compartment to the large filter previously suggested, and with a tank so constructed, unless it were hit directly at either end, puncturing the whole of the compartments, sufficient petrol would remain in the undamaged parts to carry the machine back to earth, as a frontal or angular hit would leave some few tanks still unpunctured.

B. C. WOODWARD.

#### LUBRICATING BOWDEN WIRES.

Sir,—Regarding the matter mentioned by “The Critics” in the issue of July 5th, does not the whole trouble of breakages arise from difficulty of lubricating the inner cable? I enclose a sketch of a method I have used for some years, riding every day, in all weathers, without a broken wire.

A—means of lubricating the inner cable

Also, why cannot the outside levers be fixed to the bar by small studs and nuts, similar to those on the  $2\frac{3}{4}$  h.p. Douglas?—then they cannot twist on the bar.

If manufacturers will insist on fitting inverted levers for neatness, then they should provide some method of lubricating the wire for the first foot from the lever and not trust to oil running uphill to do it. All breakages seem to start in that distance.

These were fitted on the highest point of the casing, which was cut and shortened by the amount A. Ends were wrapped with insulating tape.

YORKS.

Denmark Hill.

## AN APPRECIATION OF THE P. AND M.

Sir,—I can thoroughly endorse the statement of Mr. B. Marians as to the speed capabilities of the P. and M. solo mount when geared 4.8 to 1. On one of my machines out here I accomplished a ride of 56½ miles (by speedometer on six-cylinder Daimler) in 1h. 40m., starting at 5.30 a.m., and arriving at my destination at 7.10 a.m. This is an average speed of 34 m.p.h. The only alterations from standard were: long exhaust pipe dispensing with standard silencer, B. and B. long air inlet, extra air valve, and Lodge Aero single-point plug. Thirty miles of the journey was over indifferent *parcé*. The engine, I consider, is the most powerful and coolest running 3½ h.p. that I know. In conclusion, I must state that I have no connection with the firm of Phelon and Moore, except as a very satisfied user of their products.

B.E.F.

1712, R.F.C.

## BRITISH MAGNETOS.

Sir,—Now that the day of the German magneto is over and the British instrument has come into its own, I venture to point out a slight improvement that I suggest should be incorporated on all models.

The parts to which I refer are the aluminium end plates. These in several cases have many excrescences, such as flanges round the circumference and embossed initial letters denoting the make of the instrument.

Now personally I think nothing is more pleasing to the eye than a polished aluminium surface, and these excrescences to which I have referred prevent the magneto being easily cleaned. The Bosch has no protuberances, and when polished is only marred by the word "Bosch" incised on the aluminium.

I should like to add that I am the satisfied owner of a British M.L. magneto.

P. GROVE.

## AMERICAN GIRL RIDERS.

Sir,—The writer has just finished reading your issue of May 17th, and was pleased to see a note on page 449 telling of the activities of Milwaukee motor cycle riders in assisting the local military officers to carry out Government orders that all wireless stations be dismantled.

There is an interesting sequel to your story. Two of the motor cyclists who took part in this search for radio outfits in Milwaukee were girl drivers, the Misses Crystal Haydel and Lillian Harwin, both of whom are veteran motor cyclists, and both honorary members of the Milwaukee Motor Cycle Club. Over here we make our lady drivers honorary members, which relieves them of the payment of any dues, but obliges them to act as chaperones and hostesses when the club has any social doings in its quarters.

Miss Lillian Harwin, on her 7-9 h.p. Harley-Davidson.

Thinking that some of your lady riders might be interested in seeing a typical American girl rider, I am sending herewith a photograph of Miss Harwin.

Two days after the Milwaukee motor cyclists made their reports and all the radio outfits in the city had been dismantled, Miss Harwin received an anonymous note, apparently written by the owner of a station in one of our

suburbs, which read as follows: "My dear Miss Harwin,—There are radiograms, heliograms, and pigeongrams," indicating that the writer wanted her to know that the action of Milwaukee motor cycle owners in helping to put all wireless outfits out of commission did not prevent the owners from using other means to transmit messages. Miss Harwin turned the note over to the proper authorities for investigation.

HUGH SHARP,

Secretary Milwaukee Motor Cycle Club.

## NON-RUSTABLE STEEL.

Sir,—Our company mess rejoices in the possession of a set of knives which will not rust, stain, or tarnish, however maltreated. No doubt you have met the sort I mean. Now, I do not know all the physical properties of the steel used in them—perhaps it is unsuitable for other purposes than making knife blades; perhaps, moreover, it is prohibitively expensive, though the knives are a reasonable price—but, if there is any possibility of it, I am sure a great number of motor cyclists would put up with considerable extra weight and extra cost if they could get a motor cycle made of polished steel, unplated and unpolished, which would never lose its shining surface, in spite of weather and ill-treatment.

Perhaps some of your readers who know more than I do about the properties and possibilities of this remarkable metal can tell us if my suggestion is in any way practicable.

B.E.F.

P.A.L.

## SIDECAR AND REAR LIGHTS

Sir,—It might be of interest to some of your many readers who use sidecar outfits, and at the same time experience trouble with rear lights, that some time ago I purchased an ordinary pedal cycle model Voltalite, which I fitted to my Matchless sidecar outfit for the purpose of complying with the Lighting Orders regarding sidecar and rear lighting. This wonderful little machine, after being strengthened and adapted to suit my front forks to drive off the front wheel rim, has filled the bill quite beyond my expectations. Indeed, it has given no trouble at all, but always a steady reliable light, calling for no more attention than a spot of oil occasionally at the proper ducts provided. I use an acetylene head lamp on the motor cycle and the little Voltalite head lamp on the sidecar with its steady rear light. I must have saved its cost in carbide alone, not to mention the trouble and accompanying unpleasantness. I use my machine all weathers and do a good deal of night riding in the winter. If this little Voltalite is fitted with a little thought and care any sidecarist will appreciate a good lighting apparatus as I do. I would add the usual disclaimer, and as I bought it at an agent's I do not even know the makers' address. I was, however, assured it was absolutely British, and it is marked to that effect.

I shall continue to read your splendid paper even if you are forced to put the price up to sixpence.

Lymington.

GLOW WORM.

## SHOCK ABSORBERS.

Sir,—With reference to the article by "Chinook," I have often wondered why, in the case of an outside flywheeled engine, a shock absorber has not been placed in the flywheel boss itself, insulating the rim of the flywheel from the crankshaft.

The sprocket could be fixed to the flywheel. I should suggest a shock absorber similar to the cush hub, with blocks of rubber or springs between the radial arms which project from the crankshaft and flywheel. Perhaps a combination of both, medium strength springs to take the lighter shocks and the rubber blocks to come into operation after a slight amount of movement to take the heavier shocks.

Take an instance of a high compression single pulling hard on a high gear. When the engine fires, an enormous pressure is transmitted through the big end to the flywheel. The result is the flywheel is suddenly accelerated; naturally this sudden acceleration of the flywheel takes more insulating from the transmission than the explosion pressure would from the flywheel. It would ease the dead shock to the big end bearing, and tend towards a more even torque, as this sudden acceleration on the power stroke would not be lost, as in a slipping clutch, but would be stored up in the springs and blocks to be used on the three idle strokes.

FLYWHEEL, A.S.C., M.T.

# THE HOTTEST PART OF THE ENGINE.

The Heat of the Piston Head and its Effect upon Lubrication.

A piston having a false head, above the gudgeon-pin bearing. Hot oil is thus prevented from being splashed on to the hot underside of the piston head. The piston was designed for a 400 h.p. four-cylinder gas engine by Mr. F. G. Hatch

A design patented by Mr. D. A. Pearson. The diaphragm above the gudgeon-pin is cast with the piston, the objects being to increase crank case compression (in two-stroke engines) and to prevent oil splashing into the interior of the piston.

A piston having a thin sheet metal shell or cup which surrounds the small end of the connecting rod except on the lower side. Oil has free access to the bearing, but at the same time it is prevented from being thrown on to the inside of the piston head.

ON July 14th *The Autocar* published a most interesting and instructive article on the subject of deterioration and carbonisation of the oil in the crank case by contact with the hot (possibly red hot) piston head, and the means taken to prevent this by making pistons with double heads, and so rendering this destructive contact impossible. Three pistons designed with this end in view are shown on this page, and below we give some extracts likely to prove interesting to motor cyclists from the article to which we have referred. *The Autocar* says:

When the oil is withdrawn from the crank chamber after any considerable period of use, it is always found to be dirty. Part of this foreign matter in used lubricating oil consists of what on analysis proves to be road dust, but there is a great deal besides road dust which contaminates the oil of an internal combustion engine.

If the air as it enters an engine be filtered and so freed to a large extent from dust particles, it will nevertheless be found that the oil in the crank chamber will soon become very black. The real reason for this is that the average engine is a soot-making mechanism, and most of the soot in the oil is made on the underside of the piston, where the oil splashes up from the crank chamber and is rapidly roasted and carbonised, forming soot which is washed down by the continual splashing of oil, this oil in its turn being again made into soot and washed down into the base chamber. In fact, this means that the engine is lubricated not with oil alone but with oil and carbon particles.

If the oil could be kept from the piston head, a great deal of needless wear would be saved to all the working parts of the engine, because the oil would be cooler and cleaner. Less lubricating oil would be used.

The really important advantage is the saving of wear and tear, not merely because the oil is kept free

from carbon particles, but because its temperature is kept so much lower, and it therefore not only lubricates the bearings better but keeps them cooler.

It is too often assumed that the heating up of the lubricating oil is due merely to the hot cylinder walls, but while they undoubtedly are hot, it must be remembered that the heat is carried away by the radiating fins, and consequently they are nothing like so hot as the piston. The latter is hottest at its centre, because that portion is furthest from the cylinder walls and the heat is not conveyed away sufficiently fast to the comparatively cool cylinder walls to give uniform temperature to the piston. The hot spot is, therefore, always in the middle.

Under severe stress, such as a long period of full open throttle, there is little doubt that the middle of the piston is red hot. This effect can actually be seen on large horizontal gas engines which run with an exposed connecting rod, so that one can actually look into the inside of the piston when the engine is working.

## A Severe Test.

*The Autocar* then mentions a 400 h.p. four-cylinder gas engine built by Messrs. Brown, Lindley, and Co., of Patricroft, which is fitted with a double-ended piston, and has proved so successful that even after twenty-four hours' running at full load the temperature of the oil did not exceed 140° to 150° Fahr. In other words, this engine, the design of Mr. F. G. Hatch, running indoors for a period of twenty-four hours at a time, was keeping its oil some 20° to 30° cooler than is often the case in the crank chamber of a motor car after an hour's run on a warm day with a constant current of air under the oil sump.

Mr. Hatch's study of the subject dates back over eleven years, and was commenced at the time he designed a vertical two-cylinder gas engine exhibited at the Royal Agricultural Show at Derby in June of

### The Hottest Part of the Engine.—

r896 by the makers, Messrs. E. S. Hindley and Sons. The oil consumption was not satisfactory, and was found to be very much in excess of that of horizontal engines of similar power, and eventually a splash system was introduced almost exactly the same as that still common on many motor cars, as small pins  $\frac{1}{8}$  in. in diameter projected from the big ends and caught the oil in the crank case, throwing it up to the bearings and cylinder walls. Plates were fitted over the mouths of the cylinders slotted to permit the passing of the connecting rods. Even then it was found that the pistons on the underside of the head quickly obtained a coating of carbonised oil which reached a depth of half an inch, while the temperature in the crank case oil frequently exceeded  $170^{\circ}$  Fahr.

### Experimental Designs.

Subsequently a small engine was designed with a short piston, the casting being continued at a reduced diameter to a lower piston which acted as a cross-head guide. The result of this long dumb-bell piston, which was really two pistons connected by a waist of smaller diameter, was such that there was very little likelihood of oil reaching the hot underside of the piston head under ordinary conditions of running, and the oil in the crank case never rose above  $120^{\circ}$ , and the loss of oil was practically negligible.

The comparison of these two designs brought about the natural conclusion that a great deal of oil was lost by vaporisation caused by the heat of the piston top; also that the excess of oil found on the comparatively cool cylinder walls of the usual type of engine was in reality condensed oil vapour.

The long dumb-bell type of piston, apart from certain other objections which need not be cited, was obviously more expensive to make than the simple ordinary trunk piston such as is used on motor cars and gas engines, and the problem, therefore, was to obviate the excessive oil temperature of the ordinary design. It was thought that if the temperature of the oil could be kept at or below the temperature of the engine cooling water—that is, at or below the temperature of the cylinder walls—this vaporisation would cease, and with forced lubrication the little oil which reached the cylinder walls could be dealt with by scraper rings at the bottom of the piston. It was also thought that the loss of oil vapour through the vent pipe or breather from the crank chamber would be largely obviated.

It was shown about this time (eight or nine years ago) that the actual flow of heat from the hot centre of the piston was to the cylinder walls, and that the cooling was almost entirely due to this cause. In other words, the radiation of heat through the air in the crank chamber was of very small help, as Prof. Bernard Hopkinson, of Cambridge, had shown by his experiments that when this radiation was stopped by packing the underside of a piston with slag wool, a non-conductor of heat, its heat was only increased 2%.

It is necessary to mention here that Mr. Hatch is exceedingly anxious that there should be no delusions on this matter. While he very properly regards the keeping of oil from the hot undersides of the piston heads as most important, yet he points out that in his experience he has found that oil consumption is enormously affected by factors altogether separate from

oil temperature, by far the most important of which is the quality of iron from which the cylinders are cast.

No one supposes that all the oil reaching the hot piston head is carbonised, and therefore it is that which falls back into the crank chamber which raises the temperature of the whole bulk so rapidly. Much of it, too, is vaporised, and condensed on the comparatively cool cylinder walls, thus over-lubricating them.

In a comparative test taken with the same engine with and without the dummy piston heads a difference of no less than  $43^{\circ}$  Fahr. was found on a six-hour run. Without the dummy heads the temperature of the oil in the engine reached  $170^{\circ}$ . With the dummy heads it only got up to  $127^{\circ}$ , so that the advantages of the protection of the oil from touching the hot piston heads are twofold. We not only get the greatly reduced temperature, but the oil itself is kept free from carbon. Cooler oil and cleaner oil are advantages worth striving for.

We doubt whether the temperatures are as high in a small high speed engine as in a big gas engine, but we have no data at the moment to tell us whether with such dimensions of pistons as are used in motor cars the head ever reaches a temperature as high as  $400^{\circ}$  Cent. We should be inclined to say that it never did, except under conditions such as would obtain in racing or in aeroplane engines, but the fact remains that this is the hot spot of every engine, and, although it may not be so high as  $400^{\circ}$  Cent., it is very much hotter than any other part of the engine with which the oil comes in contact.

The hot spot in the piston necessarily has a very great effect on the temperature of the crank case oil, which in long trips loses its viscosity, and is undoubtedly less satisfactory as a lubricant and a bearing cooling medium, quite apart from the fact that the constant burning of it on the underside of the piston causes a continual rain of small carbon flakes into the crank chamber.

### A Motor Cycle Piston.

In conclusion, as an instance of the heat to which pistons may attain in motor car engines when long periods of full load running are done, we may cite the experience of Mr. Louis Coatalen with some of his racing Sunbeams when he first essayed the manufacture of steel pistons. These became so hot that the slightly domed piston heads assumed a concave form, and we imagine they would scarcely have done this at a lower temperature than  $400^{\circ}$  Cent.

Mr. Coatalen overcame the difficulty by placing a support under the piston head, bearing upon the gudgeon pin. This was quite successful in preventing further serious distortion of the piston, but it had the objection of conveying more heat to the gudgeon pin bearing, though in practice there was no trouble due to overheated little ends.

It should be noted in reference to fig. 2 that the object of the inventor, Mr. D. A. Pearson, of the Peco Co., was to increase crank case compression in a two-stroke engine, and we may say that in this respect other inventions of a somewhat similar nature have been patented, but as the intention of the inventors of these has apparently been entirely centred upon the idea of increasing crank case compression, there is no need to deal with them.

# QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

## Irregular Firing.

I have a 1910 5.6 h.p. V twin motor cycle. I have much trouble with the back cylinder. The front one will start up the first turn, but the back one will not fire at all, although there is a good spark. The valves are of the overhead type. I have changed the front valve and put it into the back and the back into the front, and have done likewise with the plugs, without any success. The carburetter is a B. and B. I have had a No. 32 jet in, but I have now put a No. 31 in.—J.W.W.

The carbon brush leading to the back cylinder may be cracked, or there may be an air leak at the front cylinder induction union. Test the plugs for weakness by changing them over. Make sure the valves are free in their guides and the tappets properly adjusted. Air leakage, whether in the induction system or past the inlet valve stem, is most probably the cause of your trouble.

## Partial Seizure.

I should be very grateful for your advice on the following matter: I have a  $4\frac{1}{2}$  h.p. 1912 three-speed Quadrant with side-car, which ran well until I fitted a new cylinder and overhauled it: (1.) Thinking the carburetter was at fault, I fitted a new B. and B. semi-automatic. The engine starts fairly well and will run all right on the stand, but when on the road will pull badly for about ten miles, then suddenly pick up and run as it should do until I get to a hill, when the machine gradually loses power, getting very hot. On one occasion it got hot and stopped, but on restarting ran all right for seventy miles without a stop, but I could not do it on the return journey. The engine takes plenty of oil, and it runs on petrol. I have tried three different plugs—two Lodge and one Bosch—taken off the extension pipe from the cylinder, fitted new rings, and ground the piston in the cylinder. The rings are a rather loose fit in the grooves. The compression is good. (2.) The big end bearing has worked loose, giving about  $\frac{1}{4}$  in. side lash. Will that hurt the engine? There is no play up and down.—G.E.

(3.) Without a personal examination of the machine it is very difficult to say what causes the overheating, but we should be inclined to think that as the engine has been recently fitted with a new cylinder and piston rings and piston

are too tight a fit in the cylinder. They may be loose in the grooves and yet touch at the slots, in which case when the engine got hot they would try to expand, and tend to cause a seizure of the piston. (2.) We presume that when you refer to  $\frac{1}{4}$  in. side lash you mean that when the cylinder is removed and the connecting rod is held at the top and moved sideways there is  $\frac{1}{4}$  in. of movement at that point. If so, it is not an unusual amount; but if the  $\frac{1}{4}$  in. you refer to is where the connecting rod big end bearing works on the crank pin, then it is excessive.

## Renovating an Old Machine.

(1.) The carburetter of my 50<sup>0</sup> 5.6 h.p. twin Rex is very much battered and leaky. Could you recommend me a make most suitable for my engine, as I am contemplating buying a new one. (2.) What is the cause of the engine overheating after it has been running for two or three minutes? (3.) The thread in the crank case in which the bolt screws for holding down one of the cylinders is stripped. How can this be remedied so that the bolt will hold in? (4.) What is the cause of excessive noise and vibration? (5.) What necessary alterations should I have to make to enable me to run on paraffin? (6.) What is the cause of the plugs sooting up quickly? Would new piston rings cure this trouble? (7.) Does the law forbid me to use a small amount of paraffin or benzolene?—A.K.

(1.) It is chiefly a matter of personal choice. Any well-known make of carburetter should give good results. (2.) This may be due to too rich a mixture, worn cams preventing the exhaust valves from lifting sufficiently, poor lubricating oil, or an insufficient quantity of the latter. (3.) This trouble may be overcome by fitting a larger bolt and retapping the union, or, if there is not room for a larger bolt, screwing a steel sleeve into the aluminium so that the original bolts may be used. (4.) The cause of the excessive noise is probably valve clatter and wear throughout, and possibly exhaust noise as well, due to inefficient silencing, while the vibration is due to imperfect balancing. (5.) Fit an efficient hot air intake, and, if possible, warm the paraffin in or before it reaches the float chamber. (6.) The plugs soot up owing to over-lubrication, riding on too strong a mixture, or to slack piston rings. New rings and a new carburetter would probably cure it. (7.) Paraffin and benzolene are counted by the Petrol Control Committee as a petrol substitute, and taxed in the same manner as petrol.

## Plug Position.

I have a 2 h.p. Humber machine with the sparking plug placed over the centre of the piston. Would you tell me (1) if it would be better placed over the inlet valve, for running on petrol, (2) or if its present position would be an advantage or otherwise when running on substitute?—LIGHTWEIGHT.

(1.) The position over the inlet valve is generally accredited to be the most satisfactory; but if the sparking plug shows no signs of becoming sooted up in its present position, we hardly think it is worth while your altering it. (2.) It does not matter whether you are running on petrol or petrol substitute, the most efficient place is undoubtedly the centre of the cylinder head.

## Difficulty in Starting.

My 1912 P. and M. has of late (even in hot weather) been difficult to start from dead cold. It will, when primed, fire at once, and always, but only for a few moments, evidently whilst the petrol in the priming lasts. I have tried every possible combination of positions of the control levers, but nothing seems to make much difference. Before I can get going I have to keep on priming and pushing off until the cylinder head warms up properly, when it will continue firing and run until stopped voluntarily. It will start quite easily when not dead cold. The following remarks will be of service to you in your diagnosis of the trouble: (1.) The cylinder head, piston, and ring grooves are quite free from carbon deposit (the engine has only just been down for cleaning). (2.) The magneto rocker arm is quite free, and the platinum points clean and flat. (3.) The clearance between the tappets and the valve stems is ample, and, I think, about correct. (4.) The petrol feed system is quite clear and clean, and the jet has never been altered. (5.) I always flood the carburetter before attempting to start. (6.) The petrol level is about correct. In conclusion, I have plenty of power, and the machine runs well when once started, firing evenly, and giving no trouble whatever.—A.H.P.

The trouble is probably due to the bad petrol on sale at the present time, or it might be due to an air leak, which may be caused by a faulty joint at the inlet pipe or induction pipe unions, or to a worn air slide in the carburetter. Try the effect of placing your hand over the air intake when starting from cold.

### Lubricating the Gear Box.

**?** I have just had my B.S.A. motor bicycle done up, and find the gear box has been filled with thick grease similar to what one sees in railway waggons. The B.S.A. people recommend this oil for the gears. Do you think the grease will do all right, or would it be better to have it out and oil put in instead?—T.P.L.

Thick grease is quite satisfactory for gear box lubrication, but gear oil is better. You might add a little engine oil to the present contents of the box; but if your machine has chain-cum-belt transmission, do not overfill the gear box, or you will be troubled by belt slip caused by oil on the belt.

### Flywheel out of Truth.

**?** I should feel grateful for your advice on the following matter. I was nine miles from home recently when my two-stroke lightweight gave out with a very loud grating noise. I examined it as best I could, and, not finding anything amiss, I tried to restart, but could not do so. The other day I took the whole engine down, and discovered that the flywheel was loose. The joint was so badly worn that I wondered how it remained on so long. The keyway in the crankshaft was also damaged. I got a new key and had the crankshaft dressed up, but I am afraid a bad job was made of it, as play was left in both the flywheel slot and keyway in the crankshaft. As a matter of fact, I do not think the flywheel was touched. Is the slot in the flywheel a tapered one, as mine is very much tapered? The repairers must have reduced the crankshaft somewhat, for the flywheel when revolved is out of truth. Would that have any effect on the running of the engine? By the way, I made a very small steel wedge the length of the key and the width of the slot in the flywheel. Kindly tell me would it hold, or could you advise any means by which I could lock the same? The flywheel is nearly  $\frac{1}{2}$  in. out of alignment.—J.C.

We do not quite see how the flywheel of your lightweight machine coming loose would cause the engine to pull up in the manner described unless the flywheel were running so far out of truth that the periphery fouled some portion of the engine or transmission. You should not have allowed any but a thoroughly qualified engineering firm to have tackled this repair. You may find that if the work has been badly done it will increase the difficulty in making a permanent repair. The key between the crank and the flywheel is not tapered, though naturally, if there were play it would wear tapered. It would certainly not be advisable to run the engine with the flywheel so far out of truth. Firstly, because the flywheel is bound to work loose again; secondly, because it would cause excessive vibration and wear; and thirdly, because it would possibly throw the crank out of truth. We would recommend you to submit the work to one of the several engineering firms which advertise in our columns that they make a speciality of engine repairs of this kind.

### Licences Required.

**?** As a reader of *The Motor Cycle* I should be much obliged if you could inform me where to get a motor licence and what I shall require. I am working in a munition factory, and have over 100 miles per week to ride on a push cycle, so am thinking of getting a motor cycle for these journeys.—A.S.

You will require: (1.) A driving licence, obtainable from the clerk of the County Council or from the Central Police Station, 5s. (2.) Inland Revenue licence, obtainable at any Post Office, £1. (3.) Registration (Central Police Station). If you buy a second-hand machine you can have the numbers transferred, which will cost you 1s.; if a new machine you will have to have it registered, which will cost you 5s. (4.) A petrol permit. The Petrol Control Committee, 19, Berkeley Street, London, W. We would advise you to draft a letter to the Committee, stating your case fully, and also stating the amount of petrol you will actually require. We would not recommend you to purchase a machine until you have obtained a petrol permit.

### Running on Paraffin.

**?** (1.) My petrol licence having run out, and as I have applied for and cannot get a new one, am I in order in using my small stock of about four gallons of petrol without a petrol licence? (2.) My motor cycle is a 1916  $2\frac{1}{2}$  h.p. single-speed two-stroke. Do you think it ought to run on paraffin; and if so, what damage might it do? (3.) I have a  $\frac{3}{4}$  in. belt, and it is always slipping. I weigh only 8 stone, and the machine will hardly pull me up a decent hill. All the covering of the belt is coming loose through it slipping. (4.) My friend sent his driving licence for renewal three weeks ago, and having received no answer, is he permitted to ride until his licence comes back?—O.P.

(1.) Yes, perfectly in order. (2.) The engine should run on paraffin, provided steps are taken to see that it is properly vaporised—by fitting a vaporiser, by taking the air in warm, and by heating up the engine first of all on petrol. You will also require more lubricating oil. Unless you follow this advice you are liable to get heavy carbon deposits and lubrication troubles. (3.) The trouble with the belt is probably due to the

pulleys being badly worn or out of alignment. (4.) He is still permitted to ride, but he should endeavour to get some sort of letter or acknowledgment from the Clerk of the Council, so that in case he is stopped he can prove to the policeman he is awaiting the return of his licence.

### Using the Compression as a Brake.

**?** (1.) Is it advisable to use the engine compression as a brake? (2.) What is the correct rate of flow for the drip-oil feed of my 1912 8 h.p. Rex-Jap? (3.) Lately my machine seems to labour greatly up hills on high gear, and I often have to change into low gear; but when I reach the top it seems to attain its usual speed. I have climbed these same hills on high gear many times before. Am I giving it too much or too little oil, or is the belt slipping?—S.A.

(1.) Yes, this is quite in order. (2.) About one drop every two seconds at twenty miles an hour. (3.) Perhaps you are giving too little oil, and possibly the engine requires to be cleaned of carbon deposit. You can easily tell if the belt is slipping by the fact that the engine revolves fast when the machine slows down.

### READER'S REPLY.

#### Firing on One Cylinder.

There was a query from "B.E.R.P." in one of your issues a month or so back [April 12th.—Ed.] as to his trouble in starting his  $2\frac{1}{2}$  h.p. W.D. Douglas. "B.E.R.P." says he has trouble with one cylinder not firing until after he has covered anything from a quarter of a mile up to two miles. I have had the same trouble with my Douglas machine. The first time it was due to the front exhaust valve, and the second time to the front tappet rod. They were gummed up with oil, and, though not immovable, the valve spring was not strong enough to return the valve to its seating quickly. The remedy is to remove the valve and clean the stem, and pull out the tappet rod to its fullest extent a few times and clean with petrol. My machine is normally a phenomenally easy starter. I never even flood the carburetter. "B.E.R.P.'s" trouble may have been the same as mine.—W. H. RICHARDS.

### RECOMMENDED ROUTES.

#### PLYMOUTH TO FALMOUTH.—D.G.S.

Plymouth, ferry to Torpoint, Antony, Polbathic, Liskeard, St. Austell, Probus, Truro, Falmouth.

#### SALFORD TO BLACKPOOL.—A.G.

Salford, Bolton, Chorley, Preston, Lytham, Blackpool. Approximately 50 miles.

#### BEARSDEN TO NORTH BERWICK.—D.R.

Bearsdan, Kirkintilloch, Kilsyth, Falkirk, Linlithgow, Winchburgh, Edinburgh, Dalkeith, Haddington, North Berwick.

#### COVENTRY TO RHYL.—S.H.

Coventry, Stonebridge, Castle Bromwich, Brownhills, Gailey, Newport, Hinckley, Whitechurch, Wrexham, Mold, St. Asaph, Rhyl.

## A Square Tread Car Cover in Miniature.

An examination of the above illustration will show that the main features of the unique principles of design and construction, which are responsible for the great success of the famous Michelin Square Tread Car Cover, are incorporated in The "Trident" Cover.

# MISCELLANEOUS ADVERTISEMENTS.

## PRICES.

**ADVERTISEMENTS** in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to **ILIFFE & SONS Ltd.**, and crossed **& Co.**

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

## NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

## DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

## SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

## MOTOR CYCLES FOR SALE.

### Abingdon.

**ABINGDON** King Dick, 1914, 3 1/2 h.p., 3-speed, clutch, new coach sidcar, all accessories, perfect; £245.—Bennett, 79, Upton Lane, Forest Gate, E.7. [5614]

**3 1/2 h.p.** Abingdon, about 1913, drop frame, 2-speed, free engine, starter, splendid condition inside and out; £220.—69, Cambridge Rd., Kilburn, N.W. [X2918]

**ABINGDON**, 3 1/2 h.p., single-speed, adjustable pulley, Bosch mag., pan seat saddle; £28; E.P. or exchange.—Service Co., 292, High Holborn, London. [5883]

### A.J.S.

**1914** 6 h.p. A.J.S., 3 speeds, etc.; £49.—Cross, Effingham Sq., Rotherham. [X2961]

**1913** A.J.S., 6 h.p., 2 speeds, and sidcar; £32.—Tuke and Bell, Ltd., Motor Dept., Carlton Engineering Works, Tottenham, N.17. [5754]

**A.J.S.**, 6 h.p., 1914 model, 3-speed, clutch, and kick start, large business sidcar, all in excellent condition; £58.—Hopkins, New St., Leamington. [X2957]

**A.J.S.**, 2 1/2 h.p., 1914, 2-speed, clutch, perfect condition throughout, not run 3,000 miles, lamp and horn complete; 28 gns.—Preece, Burghill, Hereford. [X2937]

**2 1/2 h.p.** A.J.S., 1915, 3-speed model, hand-controlled clutch and kick start, mechanically fit, smart machine, fitted with a complete set of Lucas best accessories; £45; guaranteed.—Wauchope's, 9, Shoe Lane, London. [5790]

— the name implies "Progress" and the Plug ensures it

The dictionary tells us that progress means "improvement of any kind," and the "Forward" means improvement all the time.

And remember there are illustrated in our latest catalogue a full range of models, and that Catalogue awaits your call.

Prices from 3/6 to 5/-

**Forward Motor Co.,**  
35, Forward Works,  
Summer Row,  
**BIRMINGHAM.**

## IMPORTANT NOTICE.

Owing to the August Holidays, the issue of "The Motor Cycle" for August 9th must be closed for press earlier than usual. All copy and instructions for Miscellaneous Advertisements in that issue must, therefore, be in our hands not later than first post on Thursday, August 2nd.

## DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

## MOTOR CYCLES FOR SALE.

### A.J.S.

**A.J.S.** Spares; prompt delivery.—Cyril Williams, Chapel Ash Depot, Wolverhampton. [2305]

**A.J.S.** 6 h.p. Late 1915 Twin Combination, Lucas dynamo lighting set, 4 detachable wheels, fully and well equipped, equals new in every detail; 100 gns.—Percy and Co., 337, Euston Rd., London. [5874]

**A.J.S.**, 1915, 2 1/2 h.p., 3-speed, clutch, T.T. bars, P. and H. head lamp, generator, rear lamp, tools, sound tyres, machine perfect throughout; £40.—Advertiser, 156, Gt. Portland St., W.1. [4203]

**A.J.S.** 1916 6 h.p. Twin 3-speed Combination, screen, speedometer, and lamps, a perfect machine; price and demonstration on application.—Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green. [5685]

**6 h.p. A.J.S.**, 1916, 3-speed, clutch and kick start model, detachable wheels, fitted with handsome de luxe sidcar, complete with accessories; 100 gns.; guaranteed.—Wauchope's, 9, Shoe Lane, London. [5796]

### Alldays.

**1917** Alldays Allon, shop-soiled; £40.—Jones, Garage, Broadway, Muswell Hill. [5851]

**RIDER TROWARD and Co.**, Hampstead.—1916 Alldays Allon, 2-speed; 29 gns. [5512]

**RIDER TROWARD'S**, 78, High St., Hampstead.—1914 Alldays Matchless, 4 h.p., clutch; 19 gns. [5526]

**1916** Allon (Rolls-Royce of 2-strokes), 2 1/2 h.p., 2-speed, splendid condition; £28.—Webb, 111, Bow Rd., London, E. [5653]

**1916** Alldays Allon, 2 1/2 h.p., 2-speed, clutch, in good condition; £35, near offer.—30, Park Rd., Bearwood, Birmingham. [X2751]

**OWNER** Called Up.—Alldays Allon, 1916, 2-speed; 30 gns., no offers.—Broom, 77, Marylebone Lane, Oxford St., W. [5767]

**ALLON** 2 1/2 h.p. Model de Luxe, 2-speed, kick starter, nearly new, ridden less than 500 miles; £45 cash.—W.J.M., 32, North St., Taunton. [5622]

**ALLON**, 2 1/2 h.p., 2-stroke, 1916 model, excellent condition, Lucas lighting set, horn, and accessories; £25 cash.—V. Stevens, Prescott, Stourbridge, Worcester-shire. [5667]

**ALLDAYS** Matchless, 3 1/2 h.p., 3 speeds, counter-shaft, kick starter, chain driven, coachbuilt sidcar, in real good order; £35.—Percy and Co., 337, Euston Rd., London. [5667]

**ALLON** 2 1/2 h.p. 2-stroke Motor Cycle, £38/14, or on extended payments terms, deposit £7/14, and 12 monthly payments of £2/13; 2-speed and other models also supplied.—Harrods, Motor Cycle Dept., Brompton, Rd., London, S.W.1. [5821]

## MOTOR CYCLES FOR SALE.

## Alldays.

**COLMOORE** Depots, Birmingham and Manchester, for immediate delivery of Allon 2-strokes. [X0796]  
**ALLDAYS** Allon, 2-speed, £35; single, £32/10; single-speed, new, £36; 2-speed, new, £42; 2-speed and hand clutch, new, £45; E.P. or exchange. Service Co., 292, High Holborn, London. [5884]

Only Added to £42 for a new Allon, 2-stroke, 2-speed model, or gradual payments of 1/4 down the remainder in 12 equal monthly payments.—Wanchope's, 9, Shoe Lane, Fleet St., London. [5791]

## Ariel.

**ARIEL**, new, 3 1/2 h.p., 3-speed countershaft model; £65.—Whitbread, Sheffield. [2892]

**ARIEL**, 3 1/2 h.p., 1917, 3-speed countershaft models, in stock.—Crow Bros., Guildford. [2562]

**COLMOORE** Depots, Birmingham, Manchester, Liverpool, and Leicester, for all models of Ariels. [0797]

3 h.p. Ariel Lightweight, mag., B. and B. splendid 4 condition; £7; called up.—Star, Rylands Row, Ligan. [X2969]

**ARIEL**, 3 1/2 h.p., free engine, in real good order and condition; £15.—Percy and Co., 337, Euston Rd., London. [5881]

17 Ariels in stock; immediate deliveries; deferred payments if desired.—Jones, Garage, Broadway, Newell Hill. [5852]

**ARIEL** Latest 1917 Combination, actually here; £24/10.—Lumb's, 151, High St., Walthamstow, and High Rd., Wood Green. [5694]

**ARIEL**, 3 1/2 h.p., and sidecar, 3 speeds, free engine, and extra single gear wheel, and all back fittings; price £33.—A. W. Hudson, Burham Westgate, Norfolk. [5661]

## Auto-Wheels.

**UTO-WHEEL**, splendid condition; £5/5, gift.—Barfield, 7, Fairfax Rd., Hampton Wick, Middlesex. [X2749]

**UTO-WHEEL**, 1914 model, perfect mechanical condition, good tyre; bargain, £7/10.—Advertiser, 156, Portland St., W. [5181]

**UTO-WHEEL**, B.S.A. make, Model de Luxe, December, 1915, in splendid condition; £12; can be bought by appointment any day after 5 p.m.—Dennant, Wall St., Balls Pond Rd., N.1. [5604]

## Bat.

8-h.p. Bat-Jap, in good condition, 2-speed twin, Bosch, this year's model fittings; £30, bargain; nearly new coachbuilt sidecar included.—2, Brett Rd., Stonebridge Park, Willesden, N.W. [5613]

## Blackburne.

**RIDER TROWARD** and Co., 31 and 78, High St., Hampstead.—1912 T.T. Blackburne; 23 gns. [5523]

## Bradbury.

13 Bradbury, clutch, handle starter, Philipson, perfect; £20.—Gerard, 10, Belmont Av., Edmonton. [5797]

**BRADBURY** and Sidecar, wicker, N.S.U. 2-speed gear; £35; E.P. or exchange.—Service Co., 292, High Holborn, London. [5885]

## UNOBTAINABLE!

We always have a few Machines in Stock that are not to be had for love or money elsewhere. We will let you have them for money, however, and, at present, call your attention to the following rarities:

Countershaft TRIUMPH Combination.

INDIAN Two-stroke.

F.N., 7-9 h.p., 4-cylinder, 3-speed.

BROUGH, 1916, 3-speed Countershaft.

These Machines may not be in stock when you call, as this advertisement goes in a week in advance; but, if these are sold, we shall have others equally good.

1916 New Imperial-Jap, absolutely new, never been used; first cheque for 32 gns. secures this bargain.—Julians, 84, Broad St., Reading. Biggest light car and motor cycle dealer in the South. 'Phone: 1024. [0915]

1917 Brand New Imperial-Japs, fitted with 2-speed gear and free engine, £40/19; also clutch models in stock, h.h.c. clutch, and kick starter, £7/7 extra; extended payments 2% extra.—Wauchope's, 9, Shoe Lane, London. [5794]

NEW Imperial, 2½ h.p., 2-speed gear, 39 gns.; extended payment terms, deposit £8/4, and 12 monthly payments of £2/16; clutch and kick starter models also in stock, £48/6.—Harrods, New Motor Showrooms, 118, Brompton Rd., London, S.W.1. [5819]

N.S.U.

5-6h.p. N.S.U. Engine, Bosch mag., 2 speeds; £8.—50, Etherley Rd., West Green, London, N.15. [X2754]

N.S.U. 6-7h.p. Twin, 1914, loop frame, rear springing, kick starter, 2 speeds, Millford Corvette sidecar, extra large coach body; £37/10.—Eagles and Co., High St., Acton, W.3. [X2981]

N.U.T.

RIDER TROWARD'S, 78, High St., Hampstead.—1915 T.T. Nnt-Jap, 3½ h.p. twig, a.h.v.; 37 gns. [5537]

N.U.T., 1914, 3½ h.p. twin J.A.P., 3 speeds, in real good order and condition; £32.—Percy and Co., 337, Euston Rd., London. [5882]

O.K.

RIDER TROWARD'S, 78, High St., Hampstead.—1916 O.K.-J.A.P., 2-speed, as new; 26 gns.; [5536]

O.K. Juniors.—Call and inspect at the N.W. district agent, P. J. Youngs, 2-3, The Parade, Kilburn. [0910]

1916 O.K., 2-stroke, in perfect order, as new, single-speed; £19.—Jones, Garage, Broadway, Muswell Hill. [5855]

O.K. Junior, 2-speed, new; 42 gns.; E.P. no extra, or exchange.—Service Co., 292, High Holborn, London. [5896]

P. and M.

P. and M., 3½ h.p., 2 speeds, and underslung sidecar; £22/10.—Motor Exchange, Horton St., Halifax. [5675]

WELL-KNOWN Distributing House has for immediate sale six P. and M. 1914 and 1915 models, 3½ h.p. motor cycles (2-speed chain driven), with sidecar chassis mounted with specially constructed delivery van, for which they have no further use; loading capacity 200 lbs. These cycles are recommended for their light running costs, the petrol consumption being about one-fourth compared to a Ford. Just the thing for users requiring small runabout in these days of petrol shortage. Usual equipment with each. £60 net cash. Arrangements made for expert tuition.—Box 1,087, c/o The Motor Cycle. [X2963]

## Concrete Roads.

THE roads of this country have, in most parts, been deteriorating rapidly owing to the heavy traffic consequent upon military activities and the absence of adequate repair. A certain amount of patching has been done, and town and suburban roads have been tar-sprayed. The latter process is, however, of but little use to the motor cyclist unless the pot-holes are first filled, preferably with Tarmac or some filling of a like nature. The spraying alone does nothing to mitigate the pot-hole nuisance; in fact, we are not sure that it does not make the roads more bumpy by hardening the ridges and lumps.

Any information, then, regarding the construction and maintenance of roads becomes more than usually interesting at the present time, and we welcome the report on the subject of concrete roads which has lately been prepared by Mr. H. Percy Boulnois, M.Inst.C.E., at the request of the Roads Improvement Association, and to which we referred briefly last week.

Concrete roads have been used to a considerable extent in America, and it has been estimated that there are at the present time at least 50,000,000 square yards of concrete roads in the United States. In Canada, also, this method of construction has been largely used, but in the British Isles it has been much neglected, except in some few districts, notably Chester, Dunfermline, and an experimental road near Gravesend. (Kent, by the way, is possibly our most progressive county in the matter of roads.)

The cost of laying down a concrete road, excluding the excavation and formation of the sub-base, the charge for which must necessarily vary considerably in different localities, amounts to about 5s. per square yard, but when the work is once properly done the cost of maintenance would be very trifling. Such a road, well made, would be a source of constant joy to the motor cyclist.

## The Cooling Fins of Steel Cylinders.

RECENTLY a correspondent advanced the theory that the word "radiation" is wrongly applied in connection with the cooling of a motor cycle engine—that cooling is effected not by radiation but by the impingement of the current of air on the fins of the cylinder. This observation is, perhaps, not new, yet it affords food for reflection. If in designing the fins of a cylinder radiation need not be taken into account, and the real point for consideration is the catching of the current of air in such a way that it impinges on the cooling surfaces to the best effect, then revision is certainly necessary in a great many designs. In other words, the fins may be so arranged that, though giving an efficient radiating surface, only a very small portion of this surface actually comes in contact with the rush of air—the flat twin having circular fins being a ready example. In this instance, there are no currents of air passing at high velocity between the fins, as is the case in a flat twin having longitudinal fins, yet both types of engine have proved themselves efficient as regards cooling.

There is no doubt that in the case of cast iron cylinders, in which the fins are comparatively few and far between, the disposal of the fins makes little difference so long as the total cooling surface is sufficient, yet we certainly think that when steel cylinders are used, in which the wafer-like fins are crowded closely together, they should be so arranged that the blast of cool air created by the passage of the machine circulates forcibly and freely between the fins, so as to prevent the hot air remaining latent and imprisoned in the narrow grooves. However, in the case of the flat twin with circular fins free circulation and impingement of the air over the total radiating surface could be effected by freely drilling the fins, so that the current could circulate between them.

# IDEAS: Useful and Ingenious.

Spring R. Jones

## TO PREVENT DUST IN THE ENGINE.

THE extra air inlet on many carburettors has no covering over it, hence dust is apt to get carried into the engine. To prevent this, make a square frame of thick copper wire, as shown, so as to cover the opening with plenty of fine spare. Bend the edges of a piece of fine

Preventing dust being drawn into the engine through the air intake.

copper gauze, a little larger than this, round the frame, and dish it out in the centre. Then fix it round the air chamber with another length of wire.—G.F.J., Sheffield.

## ANOTHER EASY STARTING DEVICE.

A SIMPLE, easily made, and inexpensive device for machines fitted with a Senspray carburettor, which will greatly facilitate starting up, particularly in cold weather, is a bag made of soft leather, and so fashioned as to be a nice sliding fit over the gauze

A device for facilitating starting when using a Senspray carburettor.

air-take. The gauze may be taken off for purposes of fitting, and any girl or housewife handy with the needle could make one in a few minutes. When in position over the gauze it will be found that the machine will fire with the first kick, upon which the leather cover should be drawn off by degrees, and the engine will settle down to its work. The bag can then be placed in the head lamp ready for the next occasion.—J. Dodd, Audley, Staffs.

## CONVERTING A 1912 DOUGLAS CARBURETTER.

IN the 1912 carburettor there is a separate choke tube and jet with extra air inlet. For town work it is a great convenience to have only one lever, i.e., the throttle, to manipulate. This is done by removing the throttle slide, jet, and then the choke tube. Obtain from Douglas Bros. (or agents) a jet for a 1916 Douglas carburettor. This consists of a saucer-shaped piece of brass, with air holes and the jet in the centre. In the lathe turn

Section of a Douglas carburetor converted to work automatically, showing the throttle nearly closed.

a sleeve of brass to fit inside the existing throttle slide. This should taper from the size of the jet saucer at the bottom to nothing at the top (see sketch). As shown, this is soldered inside the throttle slide. This is so arranged that when the throttle is nearly shut all the air goes through the air holes in the saucer. This increased my mileage per gallon from eighty-five to about 100. Such a jet should be chosen that unless at full throttle no air can be given. For heavy fuels solder a gauze disc across the top of the "saucer."—G.F.J., Sheffield.

## A GUARD FOR OILY CHAINS.

MANY machines without covered chains have a nasty habit of scattering oil very freely, and especially on to one's trousers. A chain guard to obviate this can be made thus: Cut out a piece of sheet metal—aluminium

An easily made chain guard.

for preference—to suit the machine in size. Bend over at the dotted lines. The end A clamps (in the case of most two-strokes) under one of the cylinder holding-down nuts. B is fixed to a bracket carried by the nut holding down the gear box, shaped as in the sketch, and made of  $\frac{1}{2}$  in. sheet iron. This does not interfere with the removal of the chain, and to riders who do a good deal of town riding in ordinary attire it will be found a useful device.—G.F.J., Sheffield.

## A TROUSER GUARD FOR A ZENITH.

THIS is a very simply made, yet very effective, guard to prevent the overalls being burnt by the back cylinder of a 5-6 h.p. Zenith. It could be fitted, of course, to any twin of similar make. Obtain first a lath, about  $\frac{1}{4}$  in. thick and  $1\frac{1}{2}$  in. wide, and also some 14 S.W.G.

A trouser guard made from 14 S.W.G. galvanised iron wire.

galvanised iron wire. Wind the wire around the lath fairly closely till about a 6 in. length of spring has been formed. Then clip one end round the inlet pipe of the back cylinder, and the other end round the exhaust pipe, and no more trouble will ensue.—G.F.J., Sheffield. [This idea is practically identical with the Dall trouser guard which has been on the market for some years.—Ed.]

OCCASIONAL  
COMMENTSBY  
"IXION"

## The Direct Belt Drive.

WHEN "K.A.H." appeals for the survival of the direct belt drive on  $3\frac{1}{2}$  h.p. machines he is up against the dislike of manufacturers to the production of two fundamentally differentiated models, up against the technical difficulties in the way of fitting such machines with variable gear, and up against the sidecar. Engine-shaft and hub gears have never been really satisfactory; single gears only appeal to a minority of purchasers. I believe the only hope for the direct belt drive depends upon price. If I saw my way to produce a first-class belt-driven single at £20 less than is charged for standard touring types, I believe I could rely on selling at least 10,000 per annum. They would be bought by "first machine" customers, by the impecunious; and by speedmen; in other words, they would appeal to a peculiar and a restricted market. But until the sidecar is finally ousted by the perfect cycle car, the variably geared, two-step drive machine has it whacked to the wide; and when the perfect cycle car arrives the lack of a sound hub or shaft gear will continue to militate against it.

## Average Speed.

THE Critics "take a far more pessimistic view of this subject than the average roadburner can endorse; but "The Critics" are right—first, because the ordinary speedometer exaggerates fearfully when its needle passes the 35 m.p.h. mark; and, secondly, because men maintain high speeds for half an hour on selected roads, and jump to the conclusion that they could keep up the same speed all day long if they were pushed. I find that the average  $3\frac{1}{2}$  h.p. solo mount usually gives its best running at about 33 m.p.h., and that most young riders keep it travelling at somewhere about that speed when they are in the saddle. But they slow down to perhaps half that speed through towns and villages, and they do not make up traffic losses in between centres of population. They lose a little more on hills, and some more on dismounts to imbibe, or to light a pipe, or to look at a view. Very few of us attain a 26 m.p.h. nett average on a full day's cross-country run. In a sixty-minute test it is the easiest thing in the world to crowd thirty-five miles or so into the hour; difficult to reel off forty; and almost impossible to cover forty-five, except with a very fast machine on carefully picked roads. After such a test no sane man cares to reel off a similar distance in a second consecutive hour. In the six-day trials most of the riders average about 30 m.p.h. between checks; and anybody who watches them will recognise that the men are not scrapping or riding to anybody's danger, but setting such a pace as the average tourist automatically adopts. A very few minutes off the saddle lower such an average amazingly, so that a holiday maker who makes brief

stoppages at every point of interest and takes his meals comfortably, finds at the end of his day that he has averaged less than legal limit, though his speedometer may have been fairly steady at just over 30 m.p.h. while he was in the saddle.

## Improving with Age.

WHEN I first rode the  $3\frac{1}{2}$  h.p. A.B.C., I fancy my only criticism was that it did not hold on to its higher gears very sturdily, showing a lack of flexibility upon them, and a tendency to prefer second gear uphill. The engine in question has now got a big five figure mileage behind it, and, curiously enough, its top gear work improves steadily. Owing to the weight which results from a complete spring suspension, a four-speed gear box and other fal-lals, it cannot, of course, climb or pick up on a 4 to 1 gear as a stripped  $3\frac{1}{2}$  h.p. T.T. with direct drive would do; but it will now hold on to fourth gear, and register over 40 m.p.h. on that gear, up hills where it asked for second gear in the days of its youth. It looks as if I had originally done the engine an injustice in thinking that it failed to combine abnormal revolutions with dogged work on a high ratio; but the engine revved so freely from the start that I never suspected it of any hidden stiffness.

## A Change-over.

FRESH from a long ride on the four-speeded spring-framed A.B.C., I went out on a light T.T. single-geared Norton, and verified some of my old opinions. For a lazy man the good heavyweight is undoubtedly the most convenient machine. It is easier to start up, because you have only to push it slowly for a foot or two, whereas the light single-gear has to be pushed fast for yards. It is far more comfortable, because its weight pins it down on the road, and it has an ampler springing system. It scores on every conceivable point bar two, namely, that the petrol consumption of the lighter mount is a good deal lower, and that the simplicity of the T.T. machine ensures the minimum of trouble. I find it rather difficult to believe that the road-racing-type of machine will be able to hold its own against the more liberal specifications, unless they are sold at a considerable vantage in price. Improvements in design and workmanship prevent complexity from being formidable, and if the T.T. is the faster mount, the full specification gives all the speed which ordinary people want on the road, and the latest types of engine afford terrific acceleration with the aid of the gear box. The Norton racer can only outpace the A.B.C. tourist on those rare pieces of road where you can get going on full throttle; and a three-speed gear, supplemented by a good driver and a willing engine, can pick up at least as fast as a crack engine which has only one gear to depend on.

## SOME HOME-DEvised SIDECAR REFINEMENTS

Many Unusual Additions Carried  
into Practice by the Rider of an  
American Excelsior.

THE machine to be described is a 1916 American Excelsior sidecar outfit. The points and details of this machine are well known, and therefore only a brief specification need be given. The engine is 7-9 h.p. (84×89 mm.); overhead inlet valves; three-speed car-type gear; interconnected hand and foot controlled clutch; Splittorf mag-dynamo electric lighting and warning system. The various incidentals or "gadgets" embodied in this machine are the subject of this article, and many of them may be described as home-designed "patents," being the work of an enthusiastic rider who is fortunate in being able to carry his ideas into practice.

Dealing firstly with the petrol-paraffin apparatus. The usual bicycle tank contains the substitute, while a half-gallon "aeroplane" tank (containing petrol) is fitted to the sidecar tube at the rider's feet. This tank is at a lower level than the carburetter, and has, consequently, to be pressure fed. This is effected by means of a bicycle pump fixed on the side of the tool box at the rear.

The tank is fitted with a pressure gauge reading up to 8 lb., which is sufficient for ten or twelve starts. The tank stopper has a piece of straight brass soldered across to give a hand grip and ensure a pressure-tight joint. The feed pipe from this tank leads to the carburetter pipe, and through a T-piece to each compression cock, with stop tap between, so that one can inject petrol into cylinders or carburetter. This does away with the necessity of opening the toolbox or disturbing the passenger to search for a petrol injector.

There is no need to tickle the carburetter with this system, as the petrol fairly "explodes" into it, thus giving it a good wash round and doing away with the necessity of draining by so

The small "aeroplane" petrol tank is attached to the sidecar tube, and is fitted with a pressure gauge.

diluting the remaining substitute as to render this unnecessary.

### Warning the Carburetter.

The carburetter, which is a Schebler, is situated between the cylinders, so that each side of the float chamber practically touches them, deriving full benefit of their warmth. The carburetter is also supplied with hot air drawn from the cylinder walls at the bottom or main air intake. The crank case release also blows hot air into the muff surrounding the air intake. The extra air (automatic) is fed by 1½ in. diameter pipe from the rear exhaust pipe. This pipe is made from a hot water angle pipe, a soda water bottle clip, and a bit of old cycle tubing.

The Splittorf mag-dynamo works in conjunction with a C.A.V. 6-volt accumulator, and supplies current for head, tail, and sidecar lamps, horn and starting switch. The front lamp is fitted with a town light of 2 c.p. and a large bulb of 12 c.p. for ordinary country work. The sidecar has a 4-volt lamp at the front and a 2-volt red rear light, running in series.

The 7-9 h.p. Excelsior (84×89), to which many useful refinements have been added.

General view of the machine. Hot air is taken from the exhaust, also from the cylinder, and utilised to aid carburation.

Mudguard and stays on sidecar, tool box, and pump to petrol tank.

## Some Home-devised Sidecar Refinements.—

The sidecar is equipped with windscreen (home-made) and dash, on which are fitted a zero centre ammeter, voltmeter, and switches. One switch—three-way—gives "off," "sidecar lights," and "voltage" respectively; the other switch shorts the bicycle circuit and defeats the small boy element, which is thus thwarted in its attempts to "blow the horn"!

Special sidecar mudguard and extra stays.

A spring wheel to the sidecar has been found absolutely necessary, as anyone who has ridden far over the present Yorkshire roads and has occasionally put his hand on the sidecar chassis will realise. The axle to which the wheel is fixed is a floating member, bushed at the bicycle end, and lubricated by a Stauffer on the under side to keep the water out. Acting in a cross lug at the outer end, and having a plunging rod through this cross lug controlled by a strong Chater-Lea spring which is adjustable, a rubber buffer is fitted to take the rebound. This has proved very effective after long test. It is perhaps specially interesting, succeeding the spring frame designs illustrated in *The Motor Cycle* of June 28th. Among its chief recommending features is its extreme simplicity, though some little experimenting was necessary before the correct spring strength was found.

## Other Sidecar Refinements.

To return for a moment to the sidecar dashboard, this is triangular in shape and hollow, the windscreen being hinged on the top. The hollow of the board is used as a wiring board, and is detachable by unscrewing four screws.

The sidecar mudguard is also worthy of note; it is a Chater-Lea, coming right down to the frame on the inside, completely shielding the passenger, while the method of fixing prevents all rattles.

To the rear of the sidecar is fitted a large box, one end having a lock-up lid for spares and tools, and also having the accumulator fitted inside in a separate teak box, locked firm and *unspillable*, but quickly detachable.

A clamp for holding down petrol cans—of which two can be comfortably carried without fear of becoming loose or rattling—is included.

Sidecar dashboard, windscreen, zero centre ammeter, voltmeter, three-way switch, and "contact" switch.

Diagram showing the method of springing the sidecar wheel.

Note will be made of the ample storage room for fuel. This is highly necessary if one does not desire to be stranded, which

under present conditions is one of the easiest of consummation. The total quantity of fuel that can be carried aboard is: Bicycle main tank,  $1\frac{1}{2}$  gallons fuel; bicycle oil tank,  $\frac{1}{2}$  gallon oil; starting tank,  $\frac{1}{2}$  gallon petrol; two tins, 4 gallons: or sufficient without replenishing to run 450 miles.

The machine itself affords a very comfortable riding position, the saddle being very low and permitting an unusually extravagant motion owing to the combination of the spring seat-pillar and well-sprung saddle.

The handle-bars are very comfortable, though scarcely wide enough for the T.T.-bar enthusiast.

The outfit is fitted with scarlet disc wheels all round to harmonise with the colour scheme, which is grey and scarlet. It looks very fine, and is always the centre of a curious and envious crowd when the rider dismounts—often to the verge of becoming embarrassing, particularly when the experts come along and diagnose the pressure gauge. Their remarks on this instrument are wide and varied.

As the mechanical pump has been found to give an unsatisfactory supply to the front cylinder, the details of the oiling system have been rearranged, and subsequently have proved entirely satisfactory. The mechanical pump now feeds main bearings only—a sight drip feed having been incorporated with the original hand pump, to which a compression spring has been fitted. This pump now feeds the front cylinder only. Part of the apparatus has

been made from an old incandescent burner, the by-pass acting as the drip feed adjuster! The crank case oil overflow feeds to the front chain and gear box respectively. The clutch is also running in oil, and thus the whole power unit—gear box, clutch, and both chains—is automatically oiled. The inner disc of the sidecar wheel is fixed permanently, while the outer disc is held simply by a bicycle bell top screwed on to the hub cap. It is instantly detachable for tyre repairs or blowing up the tyre, and in addition it has no protruding screw heads.

HUGH  
BROCKLEBANK.

Adjustable home-made windscreen.

Extra tank for petrol for starting purposes.

## HEAT IN MOTOR CYCLE ENGINES,

And a Suggestion for Using some of this Heat to Advantage.

**U**NDER this heading it is proposed to deal only with that type of engine with which the motor cyclist is generally brought in contact, namely, the air-cooled petrol engine, and to explain the conditions in which a petrol engine should run, conditions which every motor cyclist should bear in mind if he wishes to obtain the best results from his mount. It is, however, common knowledge that ideal conditions are, in practice, unattainable.

It must be understood that a petrol engine is, in effect, a hot air engine; that is, it depends for its power upon the heating of air by the combustion of petrol and the expansion thereby promoted. It is obvious, therefore, that all the heat carried off by cooling arrangements is wasted. It is found, however, that the mechanical parts of an engine cannot perform their duties at such a high temperature as would exist if the engine were not cooled. From a mechanical standpoint the engine should be kept at as low a temperature as possible. On the other hand, as little heat as possible should be wasted. The extent to which an engine is cooled is, therefore, a compromise. The temperature of any part of an engine should never exceed 500° Fahr. except instantaneously. On the other hand, it is undesirable that the cylinder head should be at a lower temperature than 180° Fahr. The most efficient mean running temperature is generally about 200° to 300° Fahr. In order to keep the engine at this a great quantity of heat must be conducted away from the cylinder head and walls and from the valve pockets. This is generally effected in motor cycle engines by fins cast integral with the cylinders and exposed to the air. These fins, being of cast iron, are fairly bad conductors of heat, and are in most cases far too short.

### The Best Metal for Radiating Fins.

In practice it is found almost impossible to over-cool the cylinders of an air-cooled engine. Therefore, it is possible to improve the general running, and particularly the oil consumption, of most engines by fitting to the cylinders and valve pockets generous radiating fins of sound design. These fins should be made of a metal of high heat conductivity. The reason for this is obvious. Another quality of the metal used requires consideration, namely, the specific heat. A metal of high specific heat has the advantage of absorbing a large quantity of heat without an undue rise in temperature. The most suitable metal as regards conductivity is copper, which has a low specific heat. Aluminium has a slightly lower conductivity, but a very high specific heat, and is probably more efficient for the purpose of radiating fins than copper, although copper is preferred by some, on account of its high heat conductivity.

The method of attachment of radiating fins is rather a moot point. Many contend that sheets of metal forced in between the cast iron fins of the cylinder introduce a large bulk of metal to hold the heat generated. It is generally understood that only the temperature, and not the quantity of heat stored, affects the running of an engine. If the bulk of metal mentioned is cooled sufficiently to keep it at the required temperature it can do no harm. It does not require larger radiating fins, since the temperature being constant the heat conducted away must be equal to the heat delivered, which is the same with or without an intervening bulk of metal. One drawback, however, of a bulk of metal is that it requires a longer period of running to raise the engine to normal running temperature, since the engine has to provide a greater quantity of heat to raise the larger mass of metal to the required heat. Here, again, the question of specific heats must be considered. Obviously the metal of lower specific heat will warm up more quickly, which adds a point in favour of copper. It seems that for an engine which pulls moderately well while cold aluminium radiating fins are the better, while for an engine which must be raised to a fairly high temperature before it will give reasonable power copper has the advantage.

### Masses of Metal.

With regard to masses of metal about the cylinders, any such masses which are not efficiently cooled will rise to a high temperature and maintain this temperature for a considerable time. Such fittings as the valve caps, sparking plug bodies, etc., should, therefore, be provided with some cooling devices.

One of the most frequent causes of knocking is pre-ignition. Even an engine with sloppy bearings will not knock easily unless pre-ignition is taking place. Knocking almost invariably takes place when the engine is labouring and developing undue quantities of heat. Three things may cause this distressing phenomenon, the spark taking place too early, an excess of carbon deposit in the cylinder head, parts of which become incandescent, or an incandescent sparking plug point. The latter is the most fruitful cause and the hardest to cure. In the majority of sparking plugs the electrodes are rather small and pointed. The points are subjected to a very high temperature, and there is insufficient metal to carry off the heat from them. This trouble is generally cured by the use of a good single-point plug with a stout central electrode bent to approach the side of the body of the plug. In some cases this is insufficient, and in all cases matters are improved by furnishing the central electrode with a large cooling fin, as is done in racing and aero plugs.

**Heat in Motor Cycle Engines.—**

One of the most neglected parts of an air-cooled engine is the exhaust port. This should be provided with ample cooling fins to keep the temperature as low as possible. The exhaust pipe should also have some cooling device, extending for a length of at least six inches from the port. The hot gases issuing from the cylinder past the valve will then be suddenly cooled, and consequently will contract. This contraction reduces the pressure in the exhaust pipe on the principle of the condenser of a steam engine, thereby assisting the quick withdrawal of the exhaust gases from the cylinder, and, as an additional result, contributing to the problem of the efficient silencing of the engine.

**Warming the Jet.**

So far only the removal of heat from the engine has been discussed. A further question presents itself. Can we use any of this heat? Certainly; but only a small, though most valuable, part. Every motor cyclist knows that a carburetter is the better for being warmed. Firstly, the petrol pipe and float chamber should be kept as cool as possible to avoid undue evaporation. The jet, however, should be kept at a temperature just below the boiling point of the spirit used. This temperature is in the neighbourhood of

185° Fahr. This may be done by leading a lagged copper rod from the jet through the wall of the carburetter and into the exhaust pipe. The copper rod should be soldered round the top of the jet, not impeding the flow of spirit, and should be made of ample diameter. If the jet gets too hot its temperature may be reduced by filing the rod so as to reduce its cross-sectional area. The induction pipe also needs warming. This may be easily accomplished by enclosing it in a jacket connected with the exhaust pipe by a lagged copper tube and regulating tap and provided with an exit. The air supply of the carburetter should also be warmed by drawing it off the radiating fins of the cylinder. For easy starting the copper rod may be heated by means of a small lamp with perfect safety if care be taken. A carburetter so fitted up will vaporise a heavier fuel without difficulty, and its performance with ordinary petrol is distinctly improved, provided that the various temperatures are correctly regulated.

Any motor cyclist working on these lines may improve the general running and petrol and oil consumption of his mount with very little expense and labour. The attention of manufacturers of motor cycles might with considerable advantage be drawn to possible improvement in these directions.

SPEED IRON.

## AN IDEAL MOTOR CYCLE.

An Enthusiast of the Four-cylinder Engine outlines his Perfect Motor Cycle.

EVERY motor cyclist has his own ideas of what constitutes a perfect motor cycle, and the specification below is drawn up from the experiences of riding a four-cylinder F.N., the chief disadvantages of which are: Irregular running, due to a.o.i.v.'s, high petrol consumption, and noisy bevel gearing. Apart from these, this machine might practically be called perfect.

It is a peculiar thing that the four-cylinder motor cycle has never come into its own. From all appearances, however, the motor cycle de luxe will have an increased market after the war in the ranks of car owners who live in the country and have hitherto considered motor cycles only fit for young bloods.

Behold, now, the outline of a proposed Rolls-Royce motor cycle:

**ENGINE.**—Four-cylinder, each cylinder 1 h.p., mechanical inlet valves, "T" head engine, air-cooled, engine inclined so that a one-step shaft drive may be used to a helical bevel drive on the back hub, semi-automatic carburetter, enclosed valves.

**DRIVE.**—By shaft throughout, F.N. type two-speed gear box.

**OTHER DETAILS.**—Plate clutch, hand controlled, kick starter, gear-driven magneto and platform for fitting an electric lighting dynamo (to be fitted optionally at choice of buyer), broad American type handlebars (not twist grip control), rubber pneumatic hand grips, aluminium footboards, Brooks B170 saddle, Indian type spring frame, black and gold finish.

Such a machine would fulfil every desire of the most critical rider—slow running, acceleration, speed, hill-climbing and steadiness on grease, no vibration, and it would be able to take a sidecar. The four-cylinder engine would be practically silent, and with proper design should give seventy-five miles per gallon (*vide* Bébé Peugeot light car). If a sidecar were used per-

manently a heavier model with four-speed gear box should be marketed (which would necessarily not be so suitable for solo work).

C. IVOR THOMAS, 2nd Lt., R.F.A.

End view of a four-cylinder engine inclined to give straight through shaft drive.

# THE TRAINING OF A DESPATCH RIDER.

## A TWO DAYS FIELD SCHEME DESCRIBED.

**A**FTER reading the very excellent account of the training of a despatch rider in the issue of *The Motor Cycle* for 24th May, I should like to pen a short description of the two days' field scheme written from the point of view of a recruit going through this part of his training.

As one who entered a motor cyclists' training camp as a recruit, and after passing out was retained in the company for many weeks, engaged on the work of training others, I can truthfully say that I always thoroughly enjoyed these schemes, as they provided an entire change of scenery, were full of life and bustle, and brought new experiences every time. Whatever the weather—rain or shine—however bad the roads—mud or snow—I was always ready for Thursday morning to come round.

### Before the Start.

Picture with me the scene on a Thursday morning. Everywhere hurry and bustle as about 200 motor cyclist recruits are getting their machines ready. Some wheeling them out of the bays—where they are kept—to the parade ground, others fastening blankets and ground sheets on their carriers, and others again drawing rations and handing round loaves, cooked joints, tins of salmon, milk, fruit, jam, and so on, to their comrades to stow away in carrier boxes and haversacks. Some of the unfortunate ones have discovered flat tyres and other defects which have to be hurriedly remedied, and many are trying to start refractory engines in order to warm them up. Everyone is asking questions. "Where is the scheme? Do we concentrate at Abingdon or Thame?" says one. Another chimes in that he expects this is the week to go to St. Ives, and a third suggests it might be Beaconsfield. While this is going on a corporal is handing out maps, and this gives some idea of the direction of the scheme. On the way down to the parade ground machines are being rapidly booked out, and on the parade ground itself the work of lining up the machines has commenced.

### Preparations Complete.

We find our marker and learn that we are the Fourth Corps, and the majority of us are undoubtedly pleased we are on a corps, as we see we have more D.R.'s than the divisions, and on telling our friends in the divisions this, they reply that we shall have three times as

much work as the divisions, so we wonder whether we are the better off after all. However, we are very keen and want to pass out, so we do not mind the work.

"Tion!" says the "Esses Emma," and the heels of 200 recruits come together with a click, like one man, each standing by his machine and ready for the road. We are told that we are to proceed to Benson by routes given to us, which are not all the same, although they all lead to the point of concentration. We now find that, instead of driving on main roads, as the majority of us have always done, we have to proceed on second and third-class roads by devious routes. We have by this time learned a little about map reading, and notice a good many contour lines crossing and recrossing our route, so we know what to expect.

Off we go, the "army" first, then the corps to which we are attached, and lastly the divisions. We are sent off singly at about thirty-yard intervals. Laughing at others attempting to start cold engines is great sport, but before we know where we are it is our turn to start, and, tickling the carburetter vigorously, nay, almost feverishly, we give one big push, and our Zenith fires, and we are away smartly, slowly running the gear up to top. We know the first few miles of the road, over which we have previously route marched, and, the machine pulling well, we feel happy as sandboys. Presently our attention is taken reading the map and watching the character of the country, looking for landmarks, such as churches, windmills, woods, etc., and carefully checking them with the map to ensure keeping on the right route. This we do whilst riding.

### A Bit of Bad Road.

Many of the roads on the map marked as second and third-class turn out to be mere field tracks, and presently we get into some deep ruts and take a toss. This bit of so-called road seems absolutely unride-

able, so we stop awhile to see how some of the others get on. A Douglas rider just gets through, followed by another, who thinks it is "easy," and comes off. A B.S.A. takes it at walking pace on low gear and waddles through corkscrew fashion. A rider on a Triumph comes howling along in fine style, but much too fast, and then suddenly comes to grief. After watching a few more get

A good deal of discussion has taken place recently respecting the dangers of lorries to despatch riders. Needless to say, ideal conditions, such as the illustration shows, do not obtain in France near the fighting line.

# NORTH BRITISH CLINCHER

## Motor Cycle TYRES

*Riding on "Clinchers"  
is Real Comfort*

CLINCHER Tyres will carry you out to the country or the sea-side with the maximum comfort and minimum tyre-trouble.

For "Clinchers" are remarkably resilient and yet extremely durable and puncture-tough. That is because, in their manufacture, only the best materials are used, and the most modern and efficient machinery employed. These things count "in the running" and ensure that extra comfort and reliability which make every trip a pleasure.

Clincher Tyres are made to maintain the sixty years' reputation of The North British Rubber Company—and they do so by giving the utmost service and fullest satisfaction. They are made at Castle Mills, Edinburgh — the Largest Rubber Factory in the Empire.

**Stockists Everywhere.**

THE NORTH BRITISH  
RUBBER CO., LTD.,  
Edinburgh, London, and Branches.

**The Training of a Despatch Rider.—**

through and a good many more come off, we push on again, and are soon on better roads and quickly approaching the rendezvous. As the roads improve the pace becomes faster, and here and there we see men stopped by the roadside, pumping up, or repairing punctures, or perhaps struggling with an exhaust valve cap which refuses to budge. It is not all beer and skittles running these training machines, which have been used over and over again by different recruits since the beginning of the war, or scrapped by one authority and rebuilt to provide recruits with experience. However, we arrive at the point of concentration, and our machines are again lined up in units, and we break away for about half an hour. Everyone has a tale to tell of his experiences on the run. Some have lost their way, others had this trouble and that, and many of the first-week men, quite new to the game, have not yet arrived. We watch them coming in one or two at a time. Look, who is that coming in with a roar like an aeroplane on a Duggy with low gear in? We go over to chip him about it, and find out that he is not aware of the existence of a change-speed gear box on his machine, and has run the whole way on low. Poor engine, what a gruelling it must have had, and doesn't it smell hot? After assuring him that he will pass up to second week all right if the sergeant sees his engine, we leave him to think it over, and drop into a little shop for a cup of tea.

Here again all is hurry and bustle. The poor woman is only used to serving one customer at a time, and with a shop full of the boys all asking for different things at once she is utterly bewildered. However, we get served in time, and shortly we fall in again and our unit is ordered to another place to open a signal office.

**Opening Office.**

We now begin to feel important. There are only eighteen of us and a sergeant, and we represent a corps. This seems real. We are on our own, and are expected to show our smartness by the rapidity with which we can open office and get into communication with other units. A few minutes' run and we are at our destination. We fix the signal service flag over the door of the inn we have chosen for our headquarters, our machines are lined up outside, and the more experienced members are chosen for the office work, and soon get busy with the messages that

we have opened office at such and such a time. We are eager that our opening message shall be timed earlier than the others, and we are soon busy carrying these messages to our divisions and to A.H.Q. For an hour or so we are busy carrying messages backwards and forwards on the same roads till we know every inch of the district and the natives are well aware that we have "arrived." One of our number is asked by a "civvy" what we are doing, and volunteers the information that the enemy are supposed to be attacking the Thames Valley, and we are the signals of an army advancing to meet them. This news quickly spreads round the countryside, and, getting somewhat distorted and exaggerated, we are presently asked if it is really true that the Germans have landed at Wapping and are coming up the river in barges!

We eat our rations as best we can between runs, which keep us going practically the whole time. We are fortunate in having all the rations, as if anyone is missing or delayed it is generally the man with the joint.

Ah! what is this? Operation orders to move and reopen office about six miles away by two o'clock. These orders have not been too quick in coming, and it is now 1.45, so we have to pack up hurriedly, and off we go to get our reopening messages off as promptly as possible.

**Marsh Gibbon.**

Next we are speculating as to the night position. The older hands look at their maps, and, working on the course of the scheme, suggest the possibilities of being sent to this place and that. However, when the message comes, "Marsh Gibbon," says the sergeant,

and the popularity of the place as a night office can be judged by the groans of those who have been there before. The route to this place we find very twisty and tricky, and we are now riding in the dark. Just as we are entering the village water looms up suddenly in front of us, and we are into it—a pond at the turn of the road—and, meeting some of the others, we find they have come a different way and entered the village by a different road, but they also have struck a pond in the dark. Now we know why it is called Marsh Gibbon. We report for duty and are given a run to a division, and, bearing in mind that we must find our way by the map alone and not stopping to look at signposts, we study the route thoroughly before starting, and, having memorised it, proceed to the cross roads, where we turn to the left.

Despatch riders studying maps whilst awaiting orders. Accurate map reading is an essential accomplishment of every D.R.

### The Training of a Despatch Rider.—

On approaching these cross roads there appears to be a sort of illuminated garden which for brilliance reminds one of the Palace Pier at Brighton. However, it simply turns out to be about a dozen of the boys shining their lamps on the signpost. On passing we notice that by the direction of this sign we have to go straight on, whereas we are turning to the left. Out come our maps, and arguments commence which end in our finding out that the signpost is loose in the ground and has been turned round by one of our officers to see if we are really as smart as we ought to be.

### A Car in Trouble.

Arriving back at the corps office rather late, we notice that a couple of officers have stopped with a car, and are busy apparently looking over our machines by candlelight, and on conveying this information to the others, who are now getting their blankets laid out for the night, one of the boys remarks quietly, "Oh, they are dissing our machines, are they? Where is their car?" and before we know what he really means he is out and changing over the h.t. leads on the car, working quickly in the dark, making 1 2 3 4 connect to plugs 4 3 2 1, so that the leads looked about the same, but would, of course, prevent the engine from starting. After about half an hour's shuffling round and playing the "Old Bull and Bush" through many times with the car handle, the officers called for our artificer, who, being in the know, did not find the trouble, and

eventually the officers decided to stay the night. Of course, next morning there was a general looking over of machines and many troubles to find, and eventually all were ready for the road, including the car. Breakfast over, we moved on, and by 9 a.m. were opening at a new position, this time about twenty miles on the road towards home, and we were soon busy again carrying despatches as before.

### "Some" Rider.

Looking at my docket after a run to A.H.Q., which was three miles away, I found that by docket time I had done the journey in three minutes. This made me think I was "some" rider, till I looked at the time for the return journey—fourteen minutes—when I decided it was evidently a case of "some" watches.

By 2 p.m. we were concentrated for the return journey to camp, and, all units coming together again, there was much to discuss. Why did the 18th Division take up their last position within the enemy's lines? Here comes So-and-so being towed. What is his trouble? Broken exhaust valve? Then he must have been blinding! And here is another with a seized engine—more material for courts of enquiry. And what about Bill, where is he? Oh, he will be here soon, he is afraid to go fast, as he thinks if his belt breaks his back wheel will drop out. The roll is called, all present reported, and off we go on the road home. Throttles are now opened a bit wider, as we know pay parade is the next item on the programme, and this is a very necessary ending to what has been a happy and memorable scheme. **GEORGIE.**

## A GREAT TRACK RIDE.

1,386½ Miles in Twenty-four Hours. Many Records Broken.

**I**N last week's issue there appeared, on page 89, a description, entitled "A Great Ride," of a Transcontinental trip by Alan T. Bedell, who rode from Los Angeles to New York on a four-cylinder Henderson, the distance—3,296 miles—being covered in 7 days 16 hours 16 minutes.

We now have to record a wonderful track ride, in which several track records held by Bedell were eclipsed. On this occasion Erwin G. Baker, riding a Powerplus Indian, beat Bedell's twenty-four hour track record of 1,153½ miles by covering in that time a total of 1,386½ miles (57.76 m.p.h.).

In the course of beating the twenty-four hour record, Baker incidentally broke the five hundred mile, the one thousand mile, and the twelve-hour records. He covered five hundred miles in 8 hours 38 minutes 30 seconds against the former record held by him of 9 hours 58 minutes. The thousand miles were covered in 17 hours 26 minutes 30 seconds, beating the previous record held by Bedell by 2 hours 34 minutes 12 seconds. In twelve hours Baker covered 702 miles, while Bedell had only 559 to his credit. In eighteen hours Baker covered 1,035 miles, as against 854 made by Bedell in his attempt.

The start was made promptly at 6 p.m. Tuesday, June 26th. Baker's schedule called for a stop every one hundred miles for petrol and oil, and the first 100 miles was rolled off in 96m., an average of 62½ m.p.h. This speed, not counting the stops, was kept consistently throughout the run. At every stop care-

ful inspections were made of the valves, springs, and oil feed, so that with a refill the time consumed was almost five minutes. The second 100 miles was drawing to a close when the record breaker's first trouble was experienced. His engine would miss for half a lap and then pick up its speed, but as it had only slowed him down to a little below sixty, he was signalled to complete the second century. When he stopped an examination of his petrol pipe showed where the trouble lay, and he was started off with a loss of 3m. 15s.

At 206 and 210 miles, stops for the same cause were again made necessary. The strainer was removed and the trouble eliminated. At 796 miles a collision with a rabbit almost broke Baker's right hand, and on his next stop his hand was swollen so badly that he could hardly get his glove off.

Just after the 900th mile had been passed, a heavy downpour of rain deluged the lone rider, and after a few minutes he was forced to stop, losing 11m.

At noon of the second day, eighteen hours after the start, 1,035 miles had been covered, and at the 1,236th mile the rider was signalled to sprint, and the lap was turned at the rate of 66m. per hour.

After the trial was over the motor was taken down in the presence of the referee and six disinterested parties, and when carefully measured was found to be under the measurements prescribed by the F.A.M. It was a stock Powerplus Indian, and an affidavit was secured to substantiate the claim.

### MAILS LOST AT SEA.

LETTER and parcel mails from Nigeria, Gold Coast Colony, and Gambia, containing correspondence and parcels posted during the second and third weeks of June approximately, and probably letter mails from other places on the West Coast of Africa, have been lost at sea through enemy action.

### PROTECTION FROM MUD.

A LORRY driver of the Motor Transport section with the Salonica Forces writes: "The article by 'East Coast' in *The Motor Cycle* interests me. The 'Tank Minor' monocoque is attractive, and I hope to possess a free-wheeler some day, and if such a free-wheeler as he suggests could be given us I feel sure it would become popular in a very short time. It seems to me that manufacturers either cannot or will not give us adequate shield from mud on motor cycles, so if we have a 'Tank Minor' monocoque, in which we can put our engines when we desire, there is certainly a good time coming for us motorists after the war, and that will not be long now."

### WAR SCRAP MOTOR CYCLES.

LAST week we suggested to the British Red Cross Society that better prices could possibly be obtained in France for war-worn motor cycles than in this country, since there is an abundance of motor cycles in the British Isles, whereas there is a real dearth of machines in France, so our correspondents advise us. Besides, there would be economy in the matter of carting and freight space. In replying, the Director of the Motor Ambulance Department of the British Red Cross Society advises us that the question of selling their scrap motor cycles in France has been considered, but, owing to the prohibitive duty, such a course is impracticable.

### THE TANK CORPS. ROYAL WARRANT ESTABLISHES A NEW ARMY UNIT.

THE Tank has come to stay, both the formidable war engine and the name the Army gave it when it first waddled out on the Somme, and glorified the Kaiser's soldiers. Hitherto it has been officially known as Machine Gun Corps (Heavy Branch), *The Motor Cycle* being instrumental in obtaining many thousands of recruits for this unit. An Army Order has now been issued giving particulars of a Royal Warrant authorising the formation of the Tank Corps.

The new unit of the British Army will consist of two parts—technical personnel and non-technical. The latter, both officers and rank and file, are to have the rates of pay and the conditions of service applicable to the Royal Field Artillery.

OFFICERS.—Majors, 19s. to 21s.; captain, 15s. 6d. to 17s. 6d.; lieutenant, 10s. 6d.; second lieutenant, 9s. 6d.

OTHER RANKS.—Mechanist staff sergeant-major, 6s.; staff sergeant, 5s. 3d.; technical quartermaster-sergeant, 5s. 3d.; tank mechanist sergeant, 4s. 2d. Tank mechanist, first class: Corporal, 4s.; lance-corporal, 3s.; private, 2s. 8d. Tank mechanist, second class: Corporal, 3s. 6d.; lance-corporal, 2s. 6d.; private, 2s. 2d.

Officers will be obtained by granted commissions to selected cadets from the Tank Corps Officer Cadet Battalion and from officers seconded or transferred from other units in the Army.

The following will be included in the technical section as tank mechanists, and will be graded as First or Second Class Mechanists, according to their technical efficiency.

Acetylene welders, blacksmiths, boiler-makers, copper-smiths, draughtsmen, electricians, fitters and turners, painters (camouflage), tank drivers, tractor drivers, and wheelers.

### MOTOR CYCLIST AIRMAN'S FUNERAL.

FLIGHT-LT. RONALD MORRISON, R.N., of Bickley, whose death was recorded in a recent issue, was buried on Tuesday, 17th July, at the little cemetery at Bromley Common, near the Sevenoaks Road. There were many floral tributes, one being from the aerodrome used by the deceased.

### ILLEGAL SALE OF WOUND STRIPES.

AT Old Street last week, before Mr. Wilberforce, Laura Alexander was fined £20 for selling a military cap badge, two wound stripes, and other such articles to unauthorised persons.

Captain Lowther, A.P.M., said that the sale of stripes and medal ribbons without authority had become a great nuisance. A lance-corporal and a civilian were sent to the defendant's shop in Great Eastern Street, and they purchased two wound stripes, a cap badge, and Queen Victoria and Albert medal ribbons. When he called at the shop the woman said that she did not know that she had done wrong.

The magistrate said that the distribution of these things must be stopped. The maximum penalty was £100.

Members of the Calcutta Scottish going to parade in Calcutta, India. This is now a daily event, and a number of Harleys are every day lined up near the parade ground.

## SPECIAL FEATURE

THE TRAINING OF A DESPATCH RIDER.  
SIDECAR REFINEMENTS. HEAT IN MOTOR CYCLE ENGINES.

## TIME TO LIGHT LAMPS

SUMMER TIME.

Aug. 2nd	...	...	9.16 p.m.
" 4th	...	...	9.12 "
" 6th	...	...	9.9 "
" 8th	...	...	9.7 "

## The Hastings Road.

Considering the traffic the Hastings Road is in excellent trim, although loose between Sevenoaks and Tonbridge, Riverhill being bad. From Battle, the alternate road *via* Arrow Hill is best.

## A Meet of 1,400 Motor Cyclists.

Over 1,400 motor cyclists and 5,000 spectators met at Beacon, N.Y., recently at a hill-climb. Indians, Harley-Davidsons, and Hendersons figured chiefly as the prizewinners.

## The "Un-English" Trap.

Recently a Bath magistrate, on the occasion of three restaurant proprietors being fined for exceeding the fifteenpence per meal limit, remarked, "Setting traps to catch offenders is not English. I would rather not get evidence at all than adopt such a system." Let us hope that other magistrates will make similar remarks against the "un-English" speed limit trap.

## Triumph Depot Smash.

On Wednesday a heavy motor lorry dashed on the pavement of High Road, Lee, and completely demolished the shop front of the T. J. Ross Triumph depôt. Four plate glass windows and frames, and four motor cycles, including a Triumph and Douglas, were smashed. The damage is estimated at £100. Ross thought it was another bomb! A new Matchless and Harley escaped injury.

## Short-period Licences.

The writer of the leading article in *The Autocar* of July 28th touched upon a topic of peculiar interest to hundreds of motor cyclists in khaki and also civilians. The subject was "Short-period Licences." Although we have many times suggested that men home on leave for a short period only should be permitted to use their motor cycles free of taxation, our sister journal has gone further and approached the Treasury with a view to obtaining this concession. Should this scheme be impracticable, an alternative suggestion would be the issue of short-period licences to cover a week, a fortnight, or a month. To carry this idea still further, why not one-day special permits, to enable an owner who may have laid up his motor cycle, but who wishes to give a prospective purchaser a trial run, to do so without breaking the law?

## The Motor Cycle in Australia.

The motor traders of Australia, in a protest against the proposed embargo on imports, stated that "The motor cycle in particular helps to keep the farmer's son on the land, besides enabling him to keep in touch with the markets."

## That Irresistible Hooter!

It is surprising how great is the fascination in the act of blowing a motor horn—not only in the small boy element, but often in his elders. A few days ago we noticed a column of recruits returning from a route march as they passed a motor cycle at the roadside. The bulb of the horn protruded at an inviting angle, and every other man within reach made a grab at it, with the result that the piercing toot-toot marked time with their martial tread till the whole column had passed.

The incident afforded an amusing character study for the onlooker. One could tell by the expression on the face of each man as he drew near whether or not he intended indulging in this perilous frivolity. Some looked away with bored indifference, obviously considering the act beneath them. Others hesitated and were lost, but the boyish spirit, who spotted the horn from afar and approached it with a mischievous twinkle in his eye, was well represented. In the meantime the horn wasted as much breath as would suffice for a fortnight's ordinary use.

Gnr. A. F. Jakins, of the "Tanks," winner of the 24 h.p. Triumph in the draw organised by the Newcastle-under-Lyme British Red Cross Society. Jakins has been wounded in action, and is now in a London hospital recovering from nervous breakdown and deafness.

## Putting on the Screw.

The Board of Trade Order issue July 13th, 1917, now compels all dealers in petrol to supply to the Board, through the Petrol Control Department, particulars as to purchases, sales, deliveries, appropriations, and stock-in-hand of motor spirit in such form and at such intervals as may be required. We understand that inspectors will visit the various dealers at intervals and examine the books recording all sales of petrol.

## Overseas News.

At a recent meeting of the general committee of the Pioneer Motor Cyclist Club, Christchurch, N.Z., it was stated that a special committee which had been appointed to peruse the rules of the Auto Cycle Union had met and had found therein nothing contrary to the interest of members of the Pioneer Club. The committee, therefore, were unanimous in recommending that the Pioneer Club should be linked up with the Auto Cycle Union in England.

## Motoring after the War.

Mr. Joynson-Hicks, at the annual meeting of the Automobile Association in London recently, referred to the prospects of motoring after the war. Many facturers must realise the enormous possibilities which the present conflict has shown them. He predicted a great development of the motor engine; it would in the future be far more wonderful than that of to-day. One question about which motorists would have much to say after the war was the condition of the roads. It was essential for the travelling and commercial community the existing roads which have been cut up by war lorries should be made good and new ones constructed.

## Air Climbing.

In a daily paper we read the following words: "From the very ground up quick climber is a joy . . . a little run and then a clean sweep away. Regardless of all the precepts of experience, you can turn as sharp as you climb, and turn and climb again." The motor cyclist who reads these words will at once think of a powerful motor cycle is referred to. The writer also says that: "To be 20,000 feet up with a powerful engine and a well-rigged machine is to feel a sense of power that nothing else can give." We have had no experience of flying, but we should think that the joys of a powerful fast-climbing motor cycle on a good sporting hill must come very near to the sensations felt by the pilot of a fast climbing aeroplane. Speed uphill is one of the chief joys of motor cycle riding. A machine which does not give that sense of power on heavy gradients is not, in the opinion of the average motor cyclist, worth having.

# The National War Relief Funds.

At the week-end the principal relief funds stood as follow:

The National Relief Fund (distributed £3,641,622)	£6,214,733	0	0
British Red Cross Fund	7,113,343	19	5
Tobacco Fund	134,465	0	0

# Two-stroke Lubrication Again.

Two-strokeists, whose engines are not dependent on the petrol system, should bear in mind that gummed-up piston rings not only upset the running, but that it may cause actual harm to the engine to continue running it for long periods after the rings are gummed in their grooves. This is because the leakage past the rings prevents the oil gaining the top of the piston, which, consequently, runs dry, till finally the top ring becomes literally welded in its groove.

# A Stolen Motor Cycle.

A correspondent, Mr. J. E. D'Eath, 7, Dyers Lane, Putney, London, S.W., recently advertised his motor cycle in his journal. Two men called in answer to the advertisement, gave him a cheque, which ultimately proved to be worthless, and left an address which was found to be false. The following is a description of the machine: 1914 two-stroke two-speed Clyno; engine number L230, Lucas lamps and horn, trip cyclometer, pillion seat; front tyre, Michelin 26in. x 2 1/2in.; back tyre, Hutchinson 26in. x 2in.; and dust cap missing on one side of back hub. Our correspondent gives a description of the purchaser as follows: Age about 24, height about 5ft. 7in., and has crooked nose.

# Economy in Petrol. Warning to Licence Holders by the Controller.

The Petrol Controller (Sir Evan Jones) on Monday issued the following notice with reference to the withdrawal of out-of-date motor spirit licences issued in respect of private motor cars and motor cycles:

Full duty motor spirit licences of the current series are available for private motor cars during the period May to October inclusive, and for private motor cycles during the period April to September inclusive.

Full duty licences which were issued for any prior period are hereby cancelled, and the holders of such licences are required to return them at once, whether exhausted or not, to the Petrol Control Department, 19, Berkeley Street, London, W.1.

The licence duty paid on any unpurchased portion of the quantity of motor spirit licensed will be refunded on the receipt of the licence by the Petrol Control Department.

In view of the necessity for conserving supplies of petrol to meet the necessary requirements for the essential trade and industry of the country, holders of licences are advised to exercise the utmost economy in the consumption of petrol, and to limit the use of motor vehicles strictly to purposes of absolute necessity. The attention of licence-holders is called to the fact that licences are not issued for purely private or pleasure purposes, and their use for such purposes, if brought to the notice of the Petrol Controller, may lead to their cancellation.

# Recent Appointments.

Mr. W. E. Bullock, works manager, and Mr. D. J. Parker, secretary, have been appointed directors of Singer and Co., Ltd.

# Death of a Prominent Motor Cyclist Airman.

It is with very great regret that we have to record the death of Lt. Ivan B. Hart-Davies, R.F.C., of Rugby, who was killed while flying in England last week. He was best known to motor cyclists as the holder of the John-o'-Groat's to Land's End record, the figures for which were reduced by him on more than one occasion. He also competed in the Senior Tourist Trophy Race of 1912. In June, 1913, he established an End-to-end record for a light car, choosing a Singer light car for the performance.

In all his motor cycle rides he remained faithful to the Triumph, and as an evidence of his popularity it was astonishing to see the number of friends and acquaintances who used to turn out to assist him in his record rides. Hart-Davies was a fine tall specimen of a

Lieut. I. B. Hart-Davies, R.F.C., killed last week whilst flying. Davies will be remembered by thousands of motor cyclists as an ardent enthusiast of the sport, and holder of many long-distance records.

motor cyclist, weighing, at the time of his rides, over thirteen stone, so that his records are all the more meritorious, being accomplished by aid of a wonderful vitality combined with a determination to wrest the coveted record from all comers.

To read of these performances, one would possibly imagine that he had little time to spare for other pastimes. On the contrary, however, he was an all-round athlete, a good cricketer, Rugby footballer, enthusiastic hockey player, and Scoutmaster of the Rugby patrol of boy scouts.

He was a thorough sportsman in every sense of the word, and of the very best type. His loss in motor cycling circles will be very keenly felt.

He was in his thirty-ninth year, and obtained his "wings" in August last year, being doubtless one of the oldest pilots to obtain their "wings" during the war.

The funeral took place at Southam on Tuesday last, a place where the early life of the deceased was spent, his father having been the rector of that place for many years.

# New Identification Marks.

The County of London has at present fifteen identification marks—A, LA, LB, LC, LD, LE, LF, LH, LK, LL, LM, LN, LO, LP, and LR. To these the identification mark LT has now been added. Kent, of which the identification mark was first D, then KT, has now had KN added to it.

# Quite a Curio.

There is no doubt that a certain percentage of letters from Overseas readers are not coming to hand, and one we have just received from the Gold Coast bears signs of having been immersed in water for some time. The letter contained photographs, glutinous and damp, and the envelope bears certain strange words and signs we are unable to decipher.

# The A.A. and M.U. General Meeting.

On Wednesday, the 25th ult., the annual general meeting of the Automobile Association and Motor Union was held at the Savoy Hotel, Mr. Joynson-Hicks, M.P., taking the chair.

In the course of his speech, in moving the adoption of the report, Mr. Joynson-Hicks gave some interesting figures, which had been given to him in Parliament, relating to the petrol position. With regard to petrol supplies, he pointed out that motorists had been reduced from sixteen to ten gallons per month, and from ten gallons to no gallons per month, unless they were doing war work. There was ample petrol in the world, and there would be no shortage after the war. The Shell Co. had 18,000,000 gallons of petrol stored, waiting for distribution after the war. He hoped motorists would realise that petrol prices would go down after the return of peace.

Mr. Joynson-Hicks quoted figures showing that during the first five months of the present year over 57,000,000 gallons of petrol had been imported, as against approximately 49,000,000 gallons in the corresponding period of last year.

The Chairman spoke of his confidence in the assured future of the Union, and pointed out that when peace conditions returned there would be much to be done. It was interesting to note that, in spite of the various restrictions on motoring, no less than 4,000 new members had been enrolled during the third year of this gigantic war.

Mr. Chas. MacWhirter (chairman of the Finance Committee) drew attention to the fact that the only additional item was £10,645, which had been devoted to the maintenance of those members of the staff who had volunteered in the days when we had a volunteer army. On the subscription side the Union had received £75,000. Another item he would mention was the reserve fund, which now amounted to £96,000.

# Petrol for France.

The chairman of the A.A. and M.U. stated at the above meeting that he had learned that petrol for use of the Army in France is now sent direct to that country, and, in view of this fact, he said that it would be instructive to know how the extra amount of motor spirit imported this year had been distributed, for certainly it had not been used by private motorists.

# The £100 SIDE CAR OUTFIT

*By an Officer*

**A**LL art is a compromise, whether it be the writing of a play, the creation of a statue, or the building of a motor vehicle. The best for the many must be necessarily the manufacturer's motto, and those who abuse that individual should try and bear in mind that it is just possible he knows his business, and in providing the much discussed and often scoffed at combination *de luxe* he is not doing so because he likes looking at it, or even riding in it, but because he is firmly of opinion that he can sell it. And in my opinion this provides evidence of sanity both on the part of maker and user.

## The Cheap Car.

Why this agitation *re* cheap car or expensive sidecar *de luxe*? Remember that the price under discussion is invariably £100 to £130. For that figure there is only one single car with a shred of reputation to be bought new. It is so well known that the Ford is the only machine in this class among cars that I shall not be accused of giving it a free advt. by naming it. Now, if there is one machine in the world that is everything that does not appeal to the average motor cyclist it is the Ford. Lest I should be thought to be disparaging that remarkable machine I will disarm criticism by saying I have driven one some thousands of miles, and, roughly speaking, put it in the same category as the Rolls-Royce and the larger sporting *type course* Peugeot as among the very few cars really worth the price asked for them. But can any sane and sound rider who has ever been on a first class well-tuned motor cycle find pleasure in plugging along at twenty-five miles an hour on a chug-chug Ford? It is all right for the man with a big family and moderate means, or as a tender to faster and bigger cars, or as a tradesman's delivery van (its real province in my opinion), but, as a serious touring machine, it is not to be compared with an up-to-date 8 h.p. sidecar *de luxe*. Its one pull is luggage carrying capacity: but the limitations of a sidecar are not half so serious as some might think, and a well-equipped outfit can easily carry sufficient baggage for two people for a week. If more is wanted send it on by train (I am writing with an eye on normal times).

It must not be assumed, however, that the 8 h.p. *de luxe* sidecar outfit is perfect. Far from it, but it

will get rapidly better and better after the war, and the competition of the cheap car will do the sidecar a lot of good. The weak spot in the outfit at the present time is the necessity for the driver to wear special clothing. This is a genuine nuisance in every way, and all enterprising makers should strive and strain every nerve to obviate this nuisance. We are only on the fringe of the really weatherproof motor cycle, I believe, and if water-cooling becomes more and more general on high-powered machines designed to pull heavy sidecars, as I believe it will, there is nothing to prevent almost complete protection of the driver from wind, mud, and rain, at all events up to his waist. I know many people will refuse to go with me in the argument for water-cooling, but I am convinced it will come, and some considerable experience with the very best air-cooled aeroplane engines has confirmed me strongly in this opinion. The plain matter of fact position is that air-cooling is a makeshift. It is advisable for certain reasons on aeroplanes—but the reasons have no hold when the engine is on a motor cycle.

## Unnecessary Noise.

Another serious criticism of the powerful motor bicycle and sidecar is the noise of the exhaust. It is possible to render the engines of these mounts as silent as on a small car, and no one is to blame but the buyer if he take delivery of a noisy machine. Other weak spots, such as draughtiness of the sidecar, tyre troubles, and such like, can easily be overcome by a little forethought in drawing up the specification of the complete machine before purchase. And, believe me, it is worth while to take some thought over the equipment of an outfit costing anything up to £130 initial outlay.

## Advantages of the First-class Sidecar Outfit.

It is when one has experienced both types of vehicle under discussion that one sees the good points of an outfit *de luxe*. The cheapness of operation, the negligible annual tax, not one per cent. on the capital outlay, the small petrol and oil bill and very moderate tyre bill (if suitably large tyres are fitted, say 650 x 65 mm.), and the high average speed obtainable all render a first-class outfit a joy to the owner. In any but the vilest weather it has the slow *cheap* car whacked all ends up, as the saying goes. We are

**The £100 Sidecar Outfit.—**

rapidly coming to the time when an outfit can be hosed down, thus robbing cleaning of all its horrors. Waterproof bearings, disc wheels, all black finish, waterproof magnetos, are with us now. In a few years we shall see no more nickel plate. Detachable wheels will be so quickly and easily detached that no one will think of leaving the machine on its wheels when cleaning. Simply jack it up and hose out the insides of the mudguards. With a well-designed, water-cooled twin—or dare I say four-cylinder *monobloc*—engine, there is no excuse for not affording complete protection to the power unit. I believe that we are only just on the fringe of the really perfect sidecar outfit. If anyone asked me what sort of sidecar would survive I should say the highest class and the highest class only. The cheap sidecar is horrid.

I have little faith in the double purpose outfit, solo or dual at will. One is continually hearing this ease of detachability urged as one of the virtues of a sidecar. I don't agree. A man very seldom detaches the sidecar—it is not nearly so easy as it sounds. A combination should be a combination—all the time. Whether the frames of machine and sidecar will eventually be one unit remains to be seen. Probably not, owing to the increase in difficulty and cost in carriage by train when desired. But we must take off our hats to the cheap car, because it has served to show the excellence of the *de luxe* outfits in the past by comparison, and it will by competition of, probably, the fiercest kind in the future, incite the manufacturer of the British sidecar *de luxe* to produce yet more perfect machines—especially in the way of cleanliness and silence.

## BENZOLE AS A MOTOR FUEL.

### AN IMPROVED PRODUCT TO BE EXPECTED AFTER THE WAR.

**W**HEN benzole is proposed as a fuel for internal combustion engines the natural inclination is to compare its properties with petrol. A comparison by the analyses of the two fuels, although only giving a theoretical comparison, will be interesting and possibly convincing to the uninitiated who oppose benzole as a fuel.

The following analyses are of commercial benzole and of the highest grades of petrol at present obtainable by the public.

SPECIFIC GRAVITY AS COMPARED WITH WATER 1.000 AT 60° F.					
Petrol	...	...	...	...	0.719
Benzole	...	...	...	...	0.881

#### DISTILLATION TEST IN DURTZ FLASK CONNECTED TO 18IN. LIEBIG CONDENSER.

Petrol.	Benzole.
Boiling point, 62° C.	Boiling point, 76° C.
Percentage at 90° C. = 30	Percentage at 80° C. = 23
" " 100° C. = 53	" " 90° C. = 90
" " 110° C. = 71	" " 100° C. = 95
" " 120° C. = 82	" Dry at 114° C.
" " 130° C. = 90	
" " 140° C. = 93	
" Dry at 148° C.	

The flash point of each fuel is well below 50° Fahr., but no reliable figures can be given owing to the fact that samples of each vary considerably in this respect.

The analyses given, let us examine the merits of each fuel.

The specific gravity of the petrol is lower than that of benzole. This, however, can have no effect on the running of an engine.

The distillation shows by the longer distilling range of the petrol that we have in benzole a far more homogeneous mixture. This is due to the fact that all definite compounds have a fixed boiling point, and the bulk of benzole is composed of the pure compound benzene which has a boiling point of 80° C.

The distillation also shows by the percentages given at various temperatures that 30% of the bulk of petrol distils above the temperature at which all the benzole has been vaporised. Consequently 30% of the petrol is less volatile than the benzole, and thus less easily carburetted.

To prove this point, that benzole is vaporised more easily than petrol, the following experiment was made: Ten cubic feet of coal gas was passed through a measuring meter into a small measured volume of benzole. 62% of the benzole was vaporised and carried away by the gas. Now the same process, under identical conditions, was carried out with petrol. Only 54% of the bulk was vaporised.

Coming now to practical experience with benzole it gives—

1. Absence of knocking.
2. More mileage.
3. Greater power.

The former disadvantages in the use of benzole are probably now eliminated owing to the experience gained by the many firms in their huge output for explosives. They were the absence of a system of general distribution and the presence of injurious sulphur compounds—Thiophene, carbon-di-sulphide, etc. The former will be wiped out after benzole-producing firms are released from munition work, and the latter was only found in isolated cases where the producing firm had little experience in the manufacture.

I have heard complaints made of benzole obtained from dubious sources, but not one where the source was an experienced firm.

Damage to the interior of the tank can occur only when benzole is used which has not been sufficiently treated with caustic soda after the acid washing, or when sufficient acid has not been used to extract the sulphur compounds.

The thickening of the lubricating oil is probably due to the presence of coumarone, which compound is also eliminated in thorough washing.

From the foregoing the reader must agree that benzole compares extremely well with petrol. I base my assertion on the fact that before the war many firms had little experience in the production of benzole, but now, when the Government accept nothing but the finest quality of benzole and advise on its production, they are capable of producing a clean, non-acid product.

L.A.S.

# THE DOUBLE-ACTING FOUR-STROKE.

A FOUR-VALVE ENGINE OF NOVEL DESIGN.

THE problem of obtaining more power for a given capacity has attracted every engine designer, and it is not a new departure to aim at a double action in a single-cylinder engine. To give an impulse on every down stroke, as in a two-stroke cycle, but to retain the advantages of quick and complete scavenging by ordinary four-stroke methods, is a difficult matter. The attempt is generally made with the object of obtaining in one cylinder the even torque of the flat twin. But there are many problems to solve, not the least being the troublesome question of dispelling the increased heat from the piston, for a piston under double firing action necessarily must be subjected to greater heat than the ordinary type. The risks of warped pistons, hot side, loss of piston ring temper, and seizure are all increased. Internal cooling is still in its infancy, but development in that direction may help to make the double-acting four-stroke an efficient power unit.

A new designer has commenced work on the problem, and his first engine is well on the way to its experimental stages. Mr. Leonard Hinks, director of James Hinks and Son, Ltd., of Birmingham—a firm not hitherto intimately connected with the motor cycle trade—is producing the engine we illustrate.

## A Double Piston.

There are two separate compression spaces: one in the head of the cylinder follows usual practice, the other is a little below it surrounding the piston. The firing in the top space acts direct on the piston head (the down stroke giving suction in the second space), the return stroke producing compression in the second

space (and exhausts the first space); firing in the second space acts upon the outer ring of the piston (the consequent down stroke is the suction stroke of the first space), and the return stroke exhausts the second space (and compresses the first space), thus completing a double cycle of operations in four strokes of the piston.

The peculiar shape of the piston should be noted; a small bore central piston is surrounded by and in one with a second piston, forming, in effect, a stepped piston. Six rings are necessary, the two internal ones being contractile. The area of the "step" is the same as that of the piston head, and the compression ratios are identical.

The valves are offset on either side, each pair opening into one pocket. The cams are operated by shafts on either side, driven by a train of wheels from a solid main shaft. There is no striking departure in valve construction, the standard J.A.P. type being taken as a model.

## Lubrication Difficulties.

As we mentioned previously, overheating is the chief trouble to be contended with, and we shall not be surprised if the designer finds difficulty with the central cylinder wall, i.e., that which is inserted between the two parts of the piston. Although the webs are slotted out to a considerable extent, the heat to be dissipated from the piston through this central wall to the external fins will be very great; efficient lubrication, which will be all the more necessary, will be also more difficult. The fitting up of the cylinder over the six piston rings will require no small amount of skill. Still, the proof of the engine is in its testing, and we shall await developments with interest. If it

A small central piston is surrounded by one of a larger bore, and forms a complete unit.

A double-acting four-stroke engine designed by Mr. Leonard Hinks, of Birmingham.

turns out to be a successful proposition its manufacture can be undertaken in large quantities by the designer, who is to be congratulated for tackling a very tricky problem.

## THE WARWICKSHIRE MOTOR VOLUNTEER CORPS

COL. D. F. LEWIS, County Commandant of the Warwickshire Volunteer Regiment, has authorised the formation of a County Motor Volunteer Corps. Light cars and motor cycles (with or without sidecars) are required. The duty of the Motor Volunteers is to provide regimental transport.

Infantry drill is not necessary, but occasional meetings are held to discuss plans and to receive suggestions. A special Active Section has been organised in Birmingham for men to receive training in such subjects as map reading, field sketching, reconnaissance, despatch carrying, convoy, etc., with a view to qualifying them to fill positions as non-commissioned officers.

Petrol is provided for the corps if called up and for training purposes, and special arrangements are being made by the Priority Branch of the Ministry of Munitions for the repair of vehicles belonging to members of the Motor Volunteer Corps.

The headquarters of this corps are in Thorp Street, Birmingham.

## A TWO-STROKE EXPERIENCE.

Four Thousand Miles Satisfactory Use by a Business Man.

THE modern two-stroke motor cycle (the production of 1915, for there has been little development since) is a curious little machine in the eyes of many motor cyclists. One hears such expressions of opinion as "Noisy little petrol wasters! I've no use for them; give me a decent four-stroke any day," or, "Not so bad, perhaps, as a runabout, but no use for serious work," and so on. This is usually the result of a short experimental run on a badly-tuned machine.

In 1914-15 my business as a surveyor necessitated almost daily visits to various properties in the vicinity of a large provincial town, and I decided to make use of a motor cycle again, my previous experience having been gained some years ago, but of later years I had been more interested in cars. I had no particular preference, and just purchased the first taking model I came across, which happened to be a  $2\frac{1}{4}$  h.p. two-speed Ivy.

My first concern was petrol economy. The first gallon gave me about eighty miles, but after careful adjustments of float-level and jet (Amac carburetter), and fitting a hot air intake, the consumption was reduced to over 100 m.p.g. This must have improved considerably as the engine became run in, for the average for the whole distance of about 4,000 miles was 106 m.p.g. Lubrication by drip feed gave satisfactory results, and the oil consumption worked out at 1,320 miles per gallon.

Tyre wear was inconsiderable, the back being good for another 2,000 or more when I sold the machine with 4,000 miles to its credit.

The original Dunlop belt was used throughout without breakage and only being shortened once.

### Carbon Deposit.

The engine was taken down three times—at 800 miles, at 1,800 miles, and

Hot air intake fixed to Amac carburetter.

at 3,500 miles; only on the last occasion was decarbonisation really necessary; the top ring was stuck up (there are two rings pegged into one slot at the top and one bottom ring); it had to be broken out and a new one fitted, but the amount of carbon on the piston

head was very small. The principal deposit was around the exhaust port, and on that side of the piston head and top ring.

The only renewals during the period were a release valve (a very unusual fault), one piston ring, and a cover plate on the Albion gear box (accidentally cracked).

### Speed and Hill-climbing Capabilities

My runs were principally in town and suburban traffic, stopping and re-starting many times in a day—a fact which makes the petrol consumption even more satisfactory—and yet speed was not sacrificed. Its limit was just over 35 m.p.h., but it was not really comfortable above 30 m.p.h. My usual running speed was twenty-five and over, and a day's average would work out at about twenty to twenty-two; on a few longer runs 100 miles were covered in just over four hours: once a non-stop seventy miles was covered in  $2\frac{3}{4}$  hours.

Not unusual speeds, but a very useful average. At hill-climbing its powers were very fair. I will not pretend that it would "fairly eat up a 1 in 6 gradient"; the second speed was generally required for anything steeper than 1 in 9, but I did not find a hill it could not take on second speed, and the West Country is notoriously hilly. The stiffest climb I recollect was a hill frequently included in local club contests; commencing at 1 in 12 or 15 for half a mile, then 1 in 10 to 1 in 6 at steepest part; total length, over one mile—a very fair pull for any machine. The Ivy took it quite well on several occasions, and did not get excessively hot. Rough weather conditions gave no trouble. I recollect dodging about in narrow, dirty

Leather shield carried on stout wire supports to keep mud off chain.

Somerset lanes and field tracks for three hours in torrents of rain without an involuntary stop—in fact, the machine never ran better. Another good point was its steadiness in grease: I cannot remember a skid of any sort.

## A Two-stroke Experience.—

## Interesting Additions.

Several gadgets which I fitted up may interest other riders. The hot air intake I have already mentioned. I soon found that the driving chain needed protection from mud thrown back from the front wheel. I fixed a leather strap, 1½ in. wide, on three stout wire brackets

Undershield made from linoleum slung to hooks on the underside of footboards.

clipped under the engine cradle nuts. This answered well, being easily pulled off the supports, washed down, and replaced.

I was much puzzled to find out how mud got on to the belt; experiments with back mudguard flaps and side wings had no effect, but the fitting of an undershield cured the trouble—the mud coming from the front wheel reached the belt at the underside of the countershaft pulley. This undershield was made of a piece of stout oilcloth, slotted to fit around the fly-wheel and silencer, slung by wire loops to four brass hooks on the underside of the footboards.

I had a certain amount of trouble owing to petrol slopping out of the filler cap; this was prevented by cutting a tin disc to fit on the ledge inside the filler hole, and riveting a cork in the centre, just high enough to engage with the cap when it is screwed home. Two small holes drilled on either side of the cork gave the necessary air vent.

I experimented with plugs for some time. An ordinary Sphinx gave very fair results, but the most satisfactory running was done on a Simms plug with one of the side points removed and the central electrode cut down by an ½ in. A Sphinx with the side point removed and the central electrode flattened and bent over gave excellent running at high speeds, but was rather irregular at slow speeds, for what reason I could not determine. The engine absolutely refused to two-stroke on some plugs which were quite good in other engines.

A tin disc and a cork were fitted in the filler to prevent petrol waste.

I had no sign whatever of the notorious two-stroke rattle. I must confess that I never cured its four-stroking propensities at speeds below 11 or 12 m.p.h. on the level when the engine was practically "running light." Generally I was quite satisfied with this little machine, and I believe it is still doing good work. The Ivy proved a most satisfactory machine, but I consider that similarly good results can be obtained with any reputable make.

SURVEYOR.

## FLAT TWINS. "Ixon" and a Critic.

SINCE "Ixon" has replied to a criticism which was never published, I think I am justified in begging an extension of your courtesy for a little space in which to give your readers an idea of that which led to his article.

I originally congratulated you upon an editorial which contained a well-balanced judgment of the flat twin as compared with other engines, hailing it with relief after those exaggerations now admitted by "Ixon" in his *Apologia pro sua vita* dated July 19th, 1917.

Granting the pre-war popularity of the 350 c.c. flat twin, I take it that everyone is talking of the big ones to come afterwards. I maintained that since this is only talk, in so far as the majority of riders is concerned, there will be much disappointment if the reality does not fulfil expectations. ("Ixon's" egotism is superb when he considers that this would merely result in his own discomfiture—the most disastrous consequence would be that the development of the type would be hampered by public ridicule for years.)

There is only one large flat twin used on military motor cycles, and it does not give quite the same satisfaction as the 350 c.c. class.

I also enquired if "Ixon's" claims for the large flat twin were not based largely upon reports of engines used for stationary work in the various Services, and pointed out that since motor cycle engines do not run at a constant speed under constant load it is not safe

to conclude that units satisfactory under one set of conditions will be equally so under another set.

The faults to which I referred are based entirely upon an experience of over 1,000 motor cycles actually examined, and as the defects have been noticed to recur too frequently to be accidental they have been taken as peculiar to the type. Referring to p. 66 I ascribe (1) wholly and (2) partly to excessive r.p.m., and (2) partly and (3) and (4) entirely to the unbalanced couple in existing flat twin engines. That to which I mostly object in "Ixon's" article is the insinuation that I am a dour individual "with no sense of humour"—may I assure him that he is quite wrong?

For instance, I was intensely amused to notice that the week following my original letter "Ixon's" weekly comments were excused owing to his vacation at the seaside—it reminded me of those curiously convenient indispositions of Ministers of State in times of crisis, and although in venturing to cross swords with such an experienced journalist I only wished to prevent the damning of the flat twin by over-praise.

Having set out to cause him "furiously to think" I was compelled to abuse "Ixon" in a somewhat extravagant manner, but "may I disarm a certain amount of criticism by drawing attention to the value of exaggeration?"

I will subscribe myself as that "meticulously-minded reader in the A.S.C.M.T." WHARFEDALE.

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

#### UNIT CONSTRUCTION.

Sir,—In your issue of July 26th you publish interesting designs of engine and gear box units. At the moment I do not know the date of their origin. Two in particular, however, attract my attention, for the following reasons:

Over ten years ago I designed a combined unit, the camshaft of which acted also as a direct magneto drive and second speed; further, the gear wheels were always in mesh, and engagement obtained by balls in a hollow shaft being pressed into spherical sockets or grooves in the gear wheels.

I might mention that this model (complete) I took to the Premier Co., Coventry, and, at their request, left it there for examination. In due course it was returned. It seems strange that the next I hear about this is when I see it in your valued paper, and it appears that the gear operation was either stale or worthy of some degree of imitation. I, however, claim to be the original inventor.

I might add that this method is in use with success in machine shops, etc.

C. ADAMS.

#### SIDECAR CONSTRUCTION.

Sir,—I saw in *The Motor Cycle* of July 19th a suggested design for a streamlined sporting sidecar. Some time ago I drew a somewhat similar design for a sporting sidecar de luxe, which, though of a sporting shape, gave at the same time the maximum degree of comfort.

The average sidecar, with its high back, is, to my mind, very ugly; while, on the other hand, the sporting torpedo-

A reader's design of streamline sporting sidecar. (See letter A. Arnold.)

shaped sidecars, though pleasing to the eye, are most uncomfortable, and expose the occupant to the wind or rain from the waist upwards.

The sidecar I have drawn is of round section and made of aluminium, which can either be enamelled or left polished. It is fitted with a hood and a small windscreen. The hollow tail could be utilised as a boot for carrying tools, etc.

ARTHUR ARNOLD.

#### AN APPRECIATION.

Sir,—I feel constrained to write and thank you, on behalf of my chum and myself, for the good results which have followed upon reading your excellent paper. It was through the medium of *The Motor Cycle* that we were enabled to get into the Royal Engineers as despatch riders. We are now on draft, after having completed a course of training

which, I must say, has been most interesting and instructive. You may be interested to hear that your paper has a great vogue, and on Thursdays there is always a rush to obtain a copy from the boy who weekly visits the camp. We are going to a place which is not far south of the "line," and it will be interesting to see how the modern motor cycle stands up to the work under tropical conditions. I have always followed with great interest the discussions in motor cycle journals about Colonial models, and the opinions expressed as to ground and mudguard clearance, frame construction, etc., and I hope, upon my return, to be able to express an opinion which may, perchance, carry a little weight. So far I have enjoyed both the work and the life thoroughly.

IAN MORISON, Pioneer M.C.

#### INVERTED CONTROL LEVERS.

Sir,—Capt. Lindsay is quite unnecessarily severe in his sarcasm anent those riders who "require lever hooks to anchor themselves," etc.; and surely a rider who finds such excessive fatigue from the use of inverted levers should also be advised to "revert to pedestrianism or travel by train."

J.W.

Belfast.

Sir,—I have read many letters in your columns by Capt. Lindsay, but never before found myself unable to appreciate his point of view, if not entirely to agree with him. I find that the inverted lever comes to hand in the most convenient position for operation; the greatest movement is at the end adjacent to the two most powerful fingers, viz., the first and second, and the other two are not called upon to do any work at all. When using the ordinary lever I find that it is more comfortable to draw the hand back and again use only the first two fingers, but this is not nearly so pleasant—that is to me personally.

Really it is only a matter of individual preference, and I do not think that either lever need cause undue fatigue—at least I have never found it so—nor have the enclosed wires ever given me any trouble.

JOHN HOLLAND.

Sir,—I have been a regular reader of your valuable journal for the last six years, and have derived much pleasure, and sometimes amusement, from the correspondence columns. Never, however, have I been so amused as by the letter appearing in the issue of July 26th over the name of Capt. Lindsay on the subject of inverted levers.

I have occasionally been tempted to seek an opportunity to express my views on some of the topics discussed in your columns, but have hitherto refrained. The ludicrousness, to my mind, of the views expressed in the letter referred to invite comment. I have often read letters, etc., in your paper contributed by Capt. Lindsay, and have assumed him to be an expert, but really when he avers that most of the "hard" (!) work of operating inverted levers falls on the third and fourth fingers of the hand, it makes one wonder what is an expert.

Ask one hundred motor cyclists which fingers are mostly used in the operation, and ninety-nine of them will declare the first and second. No wonder Capt. Lindsay complains of the delicacy of touch if he seeks for it by the preponderating use of the third and fourth fingers! These are the very two fingers that do the least work.

The only point where the normal Bowden lever scores over the inverted lever is in the accessibility of the wires when they want repairing. If they are exposed to the wet, then, of course, they often want repairing; but if inverted levers are used the wires are protected, so that this point loses

much of its advantage, inasmuch as repairs are not required so often.

As regards the hands being fatigued, how is this? To what extent are the inverted levers used in the course of a hundred miles run? When you come to think it over, these levers call for very little operating unless one drives on the exhaust to a big extent.

The only qualification I claim for contesting Capt. Lindsay's remarks is that I have averaged 20,000 miles per year for the last five years, all on Triumphs, my present machine being the War Office model. A finer machine I never wish to ride.

Thanking you for providing so much interesting reading matter each week,  
A.H.F.  
Brighton.

Sir,—Capt. Lindsay, in his letter *re* inverted controls, seems to object to these on the score of *fatigue* involved in their use. May I ask him the following questions? (1.) How often is it necessary to use these levers, and what amount of fatigue is caused by them? (2.) Is there not just as much *fatigue* to be expected in the use of the other form of controls? Or has he in mind some special form of control which involved no hard labour in working it? (3.) Will he please explain to me what he means by want of delicacy—in the use of these controls?

I have ridden motor cycles since the very early years of the sport. I have ridden for hours in trials and competitions. I ride very long and trying journeys, and use the machine entirely for business purposes, and at present also for work of national importance and special police work. In spite of this I have still to experience my first *fatigue* from the use of inverted levers on my machine.

One does not play with these all the time when riding. The use of them is really a very little thing on the whole, so that one can safely say there is very little inconvenience, bar the question of replacement when wires, etc., break: but in regard to this latter, the inconvenience is very slight compared to the want of neatness, protection, etc., in the other form suggested. I ride a heavy Triumph sidecar of the War Office pattern, and after 20,000 miles I have still to replace my first broken wire. The same applies to my lightweight Triumph—18,000 still leaves the first wire to be replaced.

If riders would only remember that good machines, like good horses, want looking after, and if they would only clean their machines, and oil them sometimes, they would not get the trouble of broken parts. Capt. Lindsay and others seem to think that manufacturers must always be wrong; but surely the experience of the firms, together with the complaints they get from riders, must teach them something; and if a maker sticks to inverted controls we may be sure, as a rule, he does so because experience proves they are the best, in spite of the whims of one or two riders.

Probably the conditions under which Capt. Lindsay rides are very, very different, but I feel sure he does not suggest that the use of his control levers, because they happen to be inverted pattern, tire him out when riding, whilst a little care will always prevent many broken wires.

(REV.) R. C. MEASURES.

#### A LONG RIDE.

Sir,—I recently made the journey from here (Newburn, S.O.) to Farnborough in a day, on a two-stroke machine, much to the surprise of all my friends. I have made enquiries to find out if any one had done a longer day's ride on a two-stroke, but have not heard of any. Can any of your readers claim a longer run in one day?

It might interest some of your readers to know that I bought the machine—a 2½ h.p. Alldays Allon 1915 model—second-hand on March 4th, this year, and that ever since then I have done thirty miles a day, seven days a week, on it. I started out for Farnborough without any preliminary tuning up at 6 a.m., and arrived at Farnborough at 9 p.m. exactly. My riding time for the journey of 310 miles was 11½ hours, an average of just over 26 m.p.h. for the whole run. Petrol consumption was 85 to 90 m.p.g. I had only one involuntary stop, due to a burst back tube. It says much for the machine that not once during the whole journey did the engine show signs of flagging, as I have been told two-strokes do on a long journey. Until I possessed the Allon I rather despised the little two-stroke machine. I also returned in one day. M. TOWERS.

#### SIDECAR V. RUNABOUT.

Sir,—Discussion often arises in your valuable paper on the question of the real and only light car which a man of moderate means can buy. The trial of the Scott, which you described some months ago, will revive the latent feeling in the hearts of holders of combinations that some time in the near future they will be emancipated from their troubles. Now, I am the owner of a 6 h.p. A.J.S. combination, which for two years has been the source of joy to myself and wife. We have done three tours a year in a careful and moderate way, carrying our food and lunching on the roadside, as much for the exhilarating freedom as for the economical aspect of the question. Every week-end has also found us performing local rides of more or less distance. In all these rides I have never known what it was to be hung up in any shape or form, and the sum total of repairs during this period has been *nil*. A finer mount it is impossible to select, and it would be a good thing if some of the recent writers on the American mounts could have a season on one of these machines, and also hear the woes of their less fortunate comrades on these foreign machines. As a matter of fact, I have never met a rider of an A.J.S. who did not praise the machine in the highest terms and want nothing better.

And yet also I, in agreement with dozens of couples who ride these combinations of different makes, am heartily sick of the disadvantages of their mounts, especially when they are paying a good price for them. When the weather is wet the driver gets plastered from head to foot, and has to wear clothes of an extraordinary nature, and then cannot keep dry, while in the hot, dry days of summer both driver and passengers are covered with the dust of the road, and are almost unpresentable when they require to spend a few hours looking over a seaside resort or other place of interest. There is not the least doubt that everybody knows that you are a couple from a sidecar combination. And yet we are seeing in the papers that the firms are vying with each other in producing new models of still increasing price, with a greater horse-power and other so-called improvements, without endeavouring to tap the greatest source of all.

How many of the riders of combinations of any great horse-power, say 4½ h.p. and over, ever take their machines out solo? I venture to say that not 5% do. Well, why are the other 95% doomed to ride a sidecar combination when they do not want a solo bicycle, and heavy combinations are not now detached for housing. They are not objects of beauty; the engineering aspect is *nil*, for they are diametrically opposed to mechanical principles, and they give us no protection against the elements. No, we want a revolution in this respect, and it is to be hoped that the war will bring it.

Now, taking up the question of the Scott light car, I would welcome it, and others seem to have done so, not because I agree in many ways with the points of the vehicle, but because it could be made as reliable as the combination, with the enhanced sociability and comfort of the passengers. I would buy one for this reason, but is it as good as the Morgan? In appearance certainly not, in stability again not, and it is hard to find wherein it is an improvement, except in the matter of a three-speed gear and shaft drive. Competition on these lines, I think, would bring a model with the comforts of a car, and far cheaper to make and buy than a good sidecar combination.

I am convinced that if a firm made a speciality of some simple design on the three-wheeled Morgan lines, and made some thousands on the Ford lines, they would sell like wildfire at about £80, and if the Ford car can be produced in America at £75, surely an 8 or 10 h.p. three-wheeler could be sold for £80 here.

It must be remembered that the housing question has changed since the sidecar superseded the forecar. Then it was common to have widths of 30in., and the machines could pass through ordinary doorways.

Gradually the manufacturers made the luxurious combination wider and wider and heavier and heavier until it was no longer possible to do this and still more impossible to detach it.

Now we find the big combination as wide as, and some of them wider than, the Morgan, but still the public buy them. I should like to hear your readers' views on the above subject.

Birmingham.

MORE COMFORT.

## CARRYING A SPARE TUBE.

Sir,—Respecting the carriage of spares, many regard the handle-bars as the place of least vibration for the tube. I find the best place for this spare is on the underside of the saddle. I took the saddle off, unfastened two nuts, put in two straps, filed off the extra lengths of bolt, and then fastened in the well protected tube. With the lowest position of the saddle there was ample distance from the mud-guard. On a solo machine I consider this position to have less vibration and to be less unsightly.

Your articles "The Critics" are very attractive and instructive to me as a novice.

R. G. HOWARD.

## AVERAGE SPEEDS.

Sir,—The figures of my last long run may be interesting as bearing out what "The Critics" say of average speeds. The original log book will be sent to you if desired.

Peterhead to Chapelhall, 177 miles, 20 m.p.h. September 25th. A little petrol and oil in tank caused low speed.

Chapelhall to Londonderry, 169 miles, 22 m.p.h. September 26th. Puncture near Brough.

Londonderry to Elton, 140 miles, 22 m.p.h. September 27th. Late start caused low mileage.

Elton to Great Missenden, 72 miles, 20½ m.p.h. September 28th. Cross-country roads.

Total, Peterhead to Great Missenden, 558 miles, 21 m.p.h.

Machine: Single-cylinder 1913 James 558 c.c. combination, but with light wicker body on this run; B. and B. fixed jet.

I find a large power to weight ratio, a hot inlet pipe, and retarded ignition are the chief essentials of success with neat paraffin.

W. R. DEUCHAR.

## TWO-STROKE PISTON RINGS.

Sir,—Replying to "Piston Rings" letter in your issue of July 19th, my experience with two-stroke engines is identical with his.

I carried out extensive investigations in order to discover a complete remedy for the loss of compression after cleaning the rings.

I have met with a certain amount of success, and I find that by partially filling the piston ring grooves with a specially prepared graphite compound much better compression is obtained after cleaning than before; further, that the tendency for the rings to gum up is very considerably reduced.

My experiences of this compound have been of such a satisfactory character that I consider it desirable that data should be obtained from other users.

If "Piston Rings" would care to communicate with me I would be pleased to send a sample for him to try.

My experiments have been carried out on Peco engines, and if the results obtained are equally as good on other makes it will greatly enhance the popularity of this type of engine.

J. J. CANNON.

## KONKING ON HILLS.

Sir,—I was very interested to read in the columns of your excellent paper of H. W. Williamson's trouble with konking, which appeared in your issue of July 19th. I own an old 3½ h.p. single, which has lately developed absolutely identical symptoms to those he describes.

I have lately had my bearings rebushed, and a friend suggested that the trouble was caused by the new bearings being tight, especially after the engine had warmed up, but I was never very convinced by the idea. I may say that the konking has resulted in the big end developing a great deal of play, after only 600 miles running, since it was renewed. That bearing at least is not too tight.

F. G. G. DAVEY.

Sir,—Lieut. Williamson's query, re his 79×100 engine konking on hills, prompts me to suggest two likely causes: (1.) Excessive piston clearance or slight distortion, brought to his notice forcibly by. (2.) the konking proclivities of present-day petrol.

I venture to suggest that on benzole or good petrol these symptoms would not have arisen. To improve matters I would suggest a lowering of his top gear ratio as the simplest expedient. I have found 4½ or 4⅔ to 1 quite high enough for general road work with this engine, but I have noticed most other users of this particular machine use gears in the immediate neighbourhood of 4 to 1, or even higher.

A. LINDSAY, CAPT. R.A.M.C.

## THE WEARING QUALITIES OF FLAT TWINS.

Sir,—I have just had the engine of my A.B.C. down for decarbonising, etc., and thought the following particulars might interest your readers: The machine is a 1914 model, and has run over 7,000 miles; no single part shows the slightest signs of wear or looseness, with the exception of the rockers of the overhead exhaust valves, and only the slightest shake here. The carbon deposit collected in 2,500 miles was nowhere more than ⅛ in. thick, and the average less than ⅓ in., and it in no way affected the running of the engine, which cannot be made to konk. I think Mr. Bradshaw is to be congratulated on a really fine piece of work. The petrol consumption is about 90 m.p.g. solo and 80 to 85 m.p.g. with a sidecar, and the lubricating oil runs the machine 500 to 600 miles on the tankful of three pints capacity. The running of this machine has been a complete revelation of what motor cycling can be, although I have ridden dozens of machines since 1903, when I commenced riding. I am sorry to say I have no connection with Mr. Bradshaw's firm, for I believe I could have sold a dozen machines this month to total strangers who were interested in the machine on the road.

R. C. MEESON.

## ALUMINIUM COOLING.

Sir,—One's first impulse upon reading such a palpably misleading communication as that signed "E. V. Hammond, M.E.," is naturally to ignore it as "not worth powder and shot." On second thought, however, it seems unfair to your technical readers to do so.

It may be as well, therefore, to point out the basis of his sneer that "the whole idea is as old as the automobile industry" is no discovery of his. Had he "carefully read all your articles on the subject," as he claims to have done, he would have been aware that this fact forms the *raison d'être* of two of them, and that you have cited Patent Office records in support thereof.

Echcing Macanlay's apology for "inflicting fourth-form learning upon our readers," I beg to state that at the time the idea in question originated:

(a) "Engineers' pocket-books" were well known, and

(b) So was the melting point of aluminium.

Further, that it was matter of common (if unconscious) knowledge even then—to the engineer no less than to every old woman with a flat-iron—that

(c) The thermal properties of metals included not only the absorption and conduction of heat, but also a strong—and oftentimes inconvenient—tendency to radiate the said heat rapidly into the surrounding atmosphere.

My only excuse for calling attention to these elementary facts is that Mr. Hammond's contention depends entirely upon his ignorance or wilful disregard of them. I imagine that it must be tolerably obvious to the majority of your readers that, by the use of a close-fitting jacket of high-conductivity metal, the superfluous heat will be quickly and continuously drained from the liner and distributed throughout the mass of the jacket metal. It only remains to provide the latter with a sufficient area of properly-designed radiating surface to ensure dissipation of the heat at a predetermined rate, with the maintenance of any desired temperature, within limits, in the cylinder walls and combustion chamber.

Apart from my own experiences with the pioneer engines built on this principle, I would point out that Mr. Wardle, with three years' experience, states that "the cooling effect of the aluminium jacket was so pronounced that, when running along the road, it was easily possible to hold one's hand on the fins." Mr. Hammond, on the other hand, with the aid of an "engineer's pocket book" and no experience at all, assures us (in effect) that Mr. Wardle is mistaken: that the latter gentleman was really paving the roads with "blobs of metal." Is Mr. Wardle quite sure that it *was* the cylinder he held? Can he lay his hand on his heart and swear that he was not holding his boot-toe, or the footrest, or—horrible thought—a tankard of "Government ale, 1917"?

It is not stated by whom the "juggling with various metals" was, or is, being carried out. Possibly this is a reference to the well-known experiments of that eminent expert Professor Shinio, who is universally recognised as an adept in this class of work. The report of this popular scientist (per favour of Capt. Bruce Bairnsfather) is awaited with calm confidence, not untinctured with a natural anxiety.

R. AYTON.

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of the envelope, and should be kept distinct from questions bearing on technical subjects.

### Timing a Two-stroke.

?

(1.) Please tell me how to time a 2½ h.p. two-stroke, fitted with a Dixie magneto (fixed ignition). (2.) What is the right size of jet for such a machine, as the petrol consumption is rather high?—C.K.

(1.) The engine should be timed in the following manner: If for a hilly country, set the spark to occur at ½ in. below the top of the stroke; if for a flat country, ¾ in. from the top of the stroke; when in this position the points should be in the act of breaking. (2.) Try a 24 jet.

### Fitting Larger Tyres.

?

I have a 1915 B.S.A. sidecar combination fitted with 2½ in. tyres. Will you kindly let me know: (1.) If for bad roads it will be any advantage to fit a larger tyre to back wheel? (2.) If a larger tyre be fitted, will it make any difference to the engine?—W.H.F.

(1.) Certainly it would be an advantage to fit a larger tyre to the back wheel. Always use the largest you can fit with comfort. (2.) Fitting a larger tyre slightly increases the work the engine has to do, but not to any serious extent. A 3 in. tyre can be obtained to fit a 2½ in. rim.

### Carburettor Flooding.

?

I have a 1914 o.h.v. 2 h.p. Calthorpe Precision, fitted with a B. and B. carburettor, which has a size 26 jet. (1.) When the machine is on the stand (engine not running) the fuel (petrol and paraffin) drips from the bottom of the jet until the float chamber is empty. Is the jet the wrong size, or does the float needle require grinding in? (2.) How could I adjust the carburettor so as to take full air? If I bring the air lever to within half an inch of the throttle the engine splutters and stops. Is this the fault of the jet? (3.) After the engine has been running, and I wheel the machine forward or backward, a bluish-white smoke comes from the air port. What is the cause, and how can I remedy it?—P.N.L.

(1.) If the float chamber empties itself the needle can hardly be at fault, as it seems effectively to prevent further spirit from entering the carburettor. It does not prove that the level is too high, and we are inclined to think that there is a bad leak at the bottom of the jet. Try a new fibre washer, and test

the tiny screw which is fitted to enable the duct to be cleaned out. (2.) There is nothing at fault from the symptoms. The amount of air permissible depends upon the jet size. If your engine pulls well, leave well alone. (3.) This is a common symptom with this particular make of carburettor, and is caused by half vaporised petrol being blown back from the air intake of the carburettor.

### Remagnetising Magnets.

?

I would like to know the exact amount of wire and the gauge for remagnetising magneto magnets from a 116 volt circuit (direct current).—R.I.

We should recommend you to wrap three turns of No. 20 wire round each magnet, after having first tested the polarity of these by means of a compass. Round the north pole the wire should be wound counter-clockwise, and clockwise round the south pole of the magnet. The current should be left on for about half an hour, and the magnets should be tapped at intervals with a hammer.

### Too Large a Jet.

?

I have a 2½ h.p. Sun two-stroke motor cycle, of which consumption of petrol is too heavy, as it will only do fifty miles to the gallon. Should

I change the jet for a smaller one?—D.E.H.

You do not say what size of jet you are using, and there may be other causes for high consumption, but we should certainly recommend you to fit a smaller jet, which might not only reduce the consumption of fuel, but also cause the engine to run better. Also look carefully for leakage in tank and pipes.

### The Lighting Regulations.

?

I have just bought a 6 h.p. flat twin Humber combination, and shall be glad of your advice re lighting. (1.) Does the head light on the handle-bar in the customary position illuminate the number plate "within the meaning of the Act"? (2.) If illumination of the plate in the rear is necessary, will an oil lamp keep alight satisfactorily if fixed on the sidecar? (3.) Is an oil lamp satisfactory, apart from the amount of light, on the front near side of the car? (4.) What intensity of illumination is now permissible in Surrey?—S.J.R.

(1.) Yes, the head lamp in the ordinary position on the handle-bars complies with the regulations as regards illuminating the number plate. (2.) The illumination of the plate in the rear is not necessary, though, of course, a red tail lamp must be used. (3.) Oil lamps are usually found unsatisfactory for attachment to sidecars. (4.) An ordinary motor cycle lamp bearing one thickness of tissue paper over the lens will comply with the regulations.

### Rattle.

?

I have a Revere two-stroke. I have had it only three months, and it was new when I bought it. There was a 28 jet (B.B. carburettor) in it when I got it, and it used to four-stroke badly. I experimented with jets, and at last got it to two-stroke nicely by mixing a little oil with the petrol and using a 26 jet. A few weeks ago the bicycle began to rattle at 15 or 20 m.p.h., and very much at any speed beyond 20 m.p.h., so I got the engine taken down, and the top ring was slightly seized. I am not sure whether this rattle is in the engine or in some other part.—S.B.

To find out whether it is the engine of your machine or some loose fitting that is causing the rattle of which you complain, run the machine with free engine, or, if it is a fixed model, with belt removed, down a steep hill, and note if the rattle then occurs. It is very possibly caused by the valances of the mudguard striking the inside of the forks. If you find you trace the trouble to the engine, it is clear that you are suffering from what is known as two-stroke rattle. The cause of this has never definitely been settled. You might effect an improvement by slightly bevelling the top and bottom of the piston, so that there is no danger of this catching the edges of the ports.

**Taking Down an Engine.**

I sent my 1912 Triumph to be rebushed, and the engineer has been called up, so I have got the engine back in parts. Would you tell me how to re-time the timing side of the crank case? The pulley half, I find, comes away easily. I am sending for your book, "Motor Cycles and How to Manage Them."—G.S.T.

To remove the timing gear side of crank case you will have to detach the pinion wheel from the end of the crankshaft. This could most easily be done by means of a wheel drawer made for such purpose. Another method is to tap four wedges equidistant round the pinion and between it and the crank case. Then by means of a full nose punch give the end of the shaft a sharp tap.

**Restive Horse causes Accident.**

I have received the following letter from a man who is unknown to me: "I have been informed that it was your motor cycle that caused my horse to bolt on July 10th, causing me bodily harm to the extent I am not fully aware of yet, not talking of the damage done to my horse and cart. If you consider recompensing me, I am willing to leave it to any arbitration you wish, or, if not, I expect I will have to take legal proceedings. Hoping to hear from you in the meantime." I know nothing of this accident, except, from hearsay in this village, that I am said to have been concerned in it. I am told that complainant alleges that it occurred at a hairpin bend about two miles away. He alleges that his horse showed signs of restiveness as I came forward, and that I "shot past," and that when I was past the horse bolted round the turn, and when out of my sight the cart overturned and the man was thrown out and cut in head and hands, and the shafts of the cart broken and horse's knees cut. I have no recollection of meeting a cart at the place, and I certainly met no restive horse, nor received any signal to stop, nor saw any horse bolting, or heard of the accident happening. The road is on rising ground at the spot, and I probably was not exceeding a speed of 10 m.p.h. I believe I am not known to complainant personally, but a man who came to his assistance at the time of the accident told him I had just passed up a few minutes before. I did pass about the time the accident is said to have happened, but there were other motorists on the road the same evening. My machine has an efficient silencer, and I am an experienced and careful driver, and am in Government service.—J.L.

We have submitted your query to our legal adviser, who replies as follows: "I cannot find that any case has been decided on all fours with the facts given by your correspondent. There is a case where a dog ran out and snapped at the mare's heels, which caused her to plunge and injure herself, and it was held that the owner of the dog was liable. The position with regard to the motor cyclist is, however, very different.

If your correspondent were going along the road at a proper speed, and with an efficient silencer, he ought to succeed in any action which is brought against him. He would not be liable if the horse bolted through exceptional timidity or restiveness; and the whole question of liability depends upon whether your correspondent was properly riding the motor cycle at the time, and whether the fear inspired in the horse was under the circumstances natural and what might be expected as the result of any particular noise which your correspondent may have wrongfully caused."

**Charging an Accumulator.**

Please tell me (1) the number of 40-50 c.p. lamps a 240 volt direct current should pass through to charge a 40 ampere one hour accumulator. (2) How to tell when the accumulator is fully charged.—C.P.M.

(1.) The lamps you mention take about  $\frac{3}{4}$  ampere each. The charging rate is marked on the accumulators. This must not be exceeded, but a lower rate may be used. Four lamps will probably be sufficient. The charge will take from ten to twelve hours or more. (2.) When charged the acid will froth over, and the accumulator should register  $4\frac{1}{2}$  volts, if it be a 4 volt accumulator.

**Unsatisfactory Running.**

Would you please let me know what is wrong with my 6 h.p. twin. Recently I broke the front cylinder at the bottom where it joins on to the crank case, and got it electrically welded. Now, after going about two miles, the engine, on getting hot, starts to misfire on the least incline, and on hills misfires and stops altogether. (These hills it used to fly up.) Give it a minute or two to cool and it will go fairly well until it gets heated up again. I have fitted new exhaust valve springs. Can there be anything wrong with the magneto when the machine is going at a fair speed, as I have never touched it (of course, I oil it now and again), and I have now had it three or four years?—A.K.M.

Probably the engine requires to be run in after the repair. It is very unlikely that the magneto is at fault, and the trouble is more likely to be due to the fact that you are using an unsuitable plug, which causes pre-ignition when the work is hard. Try a good single or double-point plug with substantial electrodes.

**Enamelling a Motor Cycle.**

I have an 8-10 h.p. combination outfit, similar to the big Matchless combination. Could you give me some idea as to how much enamel I should require to re-enamel it? And could you give an idea of the procedure as regards cleaning before applying enamel? There is also another point on which I should like your opinion. The engine is a Precision 8-10 h.p. V twin. When it was last reassembled the thread on the induction pipe was crossed, and now the induction pipe will not screw tightly to the cylinder. I have packed the joint with asbestos string and bound it with copper wire. Will this necessitate a new induction pipe, and should I have much difficulty in getting one?—G.H.H.

A shilling tin of enamel should be sufficient. To make a really good job of it, you should clean your machine very carefully, polish with emery paper, and then wash with hot soda and water, and carefully dry before applying the enamel, which should be done in a place quite free from dust.

Provided that your induction pipe can be firmly fixed, and there are no air leaks, you will be able to get on without a new pipe, which would probably be difficult to obtain at the present time.

**READER'S REPLY.****A Mysterious Pulling Up.**

I notice "R.E.B.'s" trouble with his two-stroke in *The Motor Cycle* of July 19th. I myself had the same trouble with an Ivy two-stroke, viz., the machine would slow up, but on raising the exhaust it would invariably start off again. Flooding the carburetter would have the same effect. Now in my case the trouble was due to back pressure, and the permanent removal of the extension pipe to the exhaust box (together with a thorough cleaning of exhaust port, exhaust pipe, and box) set matters right. I advise "R.E.B." to try this, as I had an enormous amount of trouble, and it was a long while before I found out the remedy.—TWO-STROKE.

**RECOMMENDED ROUTES.****BURGESS HILL TO PETERSFIELD.—M.B.**

Burgess Hill, Cowfold, Billingshurst, Petworth, Midhurst, Rogate, Petersfield.

**WESTON-SUPER-MARE TO ABERCARN.—E.H.**

Weston-super-Mare, Congresbury, Flax Bourton, Clifton, Filton, Stone, Cambridge, Gloucester, Newnham, Lydney, Chepstow, Newport, Abercarn. Approximately 110 miles.

**CASTLE BROMWICH TO MINEHEAD.—J.H.**

Castle Bromwich, Birmingham, Alcester, Evesham, Teddington, Cheltenham, Painswick, Stroud, Nailsworth, Bath, Marksbury, Chewton Mendip, Wells, Glastonbury, Bridgwater, Nether Stowey, Williton, Minehead.

**ANNAN TO LONDON.—G.L.S.**

Annan, Carlisle, Penrith, Kendal, Kirkby Lonsdale, Settle, Skipton, Ilkley, Otley, Harewood, Aberford, Ferrybridge, Doncaster, East Retford, Newark, Grantham, Stamford, Stilton, Buckden, Biggleswade, Hatfield, Barnet, London.

Coventry, Dunchurch, Daventry, Towcester, Stony Stratford, Penny Stratford, Dunstable, St. Albans, Barnet, London, Greenwich, Dartford, Gravesend, Chatham, Sittingbourne, Faversham, Canterbury, Margate.

**WOKINGHAM TO AYSGARTh.—S.T.**

Wokingham, Twyford, Great Marlow, High Wycombe, Princes Risborough, Aylesbury, Winslow, Buckingham, Towcester, Northampton, Market Harborough, Leicester, Newark (by Fosse Way), East Retford, Doncaster, Ferrybridge, Aberford, Wetherby, Boroughbridge, Ripon, Masham, Aysgarth.

## AVERAGE PRICES.

WE give below the prices of second-hand machines offered for sale in the last issue of *The Motor Cycle*, and in the adjoining column the average prices based upon the latest figures available. Thus the general trend of the market is visible at a glance, though in the first column many blanks inevitably occur. This is due to an insufficient number of one model on which to base an average. The word "combination" indicates a sidecar outfit as supplied by the makers, while "sidecar" implies that the fitting has been carried out by the owner.

Make.	Year.	H.P.	Average last week.	Previous weekly average.

## Messrs. Harrods, Ltd.—New Premises.

The motor showrooms of Messrs. Harrods, Ltd., are now at more convenient premises, 118, Brompton Road—nearly opposite the main building.

## Saddle Repairs.

Messrs. Brooks ask us to make an appeal to trader and private owner alike to withhold—at least, for a period—all repairs of cycle and motor cycle saddles which are not of vital urgency.

## Dunlop Tyre Prices.

We are informed that prices for Dunlop motor and motor cycle tyres have been revised, and that copies of the revised wholesale and retail price lists were posted to the trade on 21st July.

## Robbialac.

A useful leaflet is to hand giving hints to amateurs who may be renovating their sidecar or motor cycle, together with a price list of the various productions of Messrs. Jenson and Nicholson, Ltd. These leaflets will be sent post free on application to the Robbialac Works, Stratford, London, E.15.

## Air Raids and Motor Cycle Insurance.

It may not be generally known that the ordinary motor cycle insurance policy does not cover loss in the event of damage resulting from air risks. In this connection Messrs. British Dreadnought Underwriters, Ltd., have prepared a special policy covering all loss at a very slight premium, full particulars of which Mr. Harford G. Olden will be pleased to furnish upon request.

## British v. German Trade.

A group of British capitalists and manufacturers, with live business organisation, already successfully specialising in business formerly monopolised largely by alien enemies, is prepared to co-operate in financing, manufacturing, or introducing on a large scale new lines of wares (German or otherwise). Holders of patents or others interested are invited to communicate with the Editor of this journal, who will pass over the letters to the manufacturers concerned.

## Harvey Frost and Co., Ltd.—Extension of Premises.

The West End Branch of Messrs. Harvey Frost and Co., Ltd., formerly at Charing Cross Road, has been transferred to new premises in Gt. Portland Street, where greater facilities for dealing with demonstration and instruction are now in operation. Enquiries regarding the H.F. Schools of Vulcanising Instruction, and communications intended for the West End Branch, should be addressed in future to 148-150, Gt. Portland Street, W.1. The head offices of the company remain at Gt. Eastern Street, E.C., for the present.

## New Address.

The Barnett Motor Tyre and Rubber Co., of Valley Rubber Works, Limpley Stoke, are removing to their new works and offices, Yerbury Mills, Trowbridge, Wilts.; telephone, 113 Trowbridge; telegraphic address, Vacuum, Trowbridge. These works have been equipped with the very latest machinery and plant for the manufacture of motor and motor cycle tyres, etc.

## Economic Motoring.

To lessen the cost of motoring particularly motor cycling, is the object for which most people concerned are on the look out. Messrs. J. M. Ouseley and Son have in the press a complete little book on the subject, entitled 'Economic Motoring,' which will shortly be published. The author is a well-known motorist.

## Discharged Soldiers and Sailors.

The activities of the Central Committee for Employment of Discharged Soldiers and Sailors connected with the motor industry continue.

It is hoped that the committee will obtain adequate employment for all men who apply. Meanwhile, it is in touch with a number of employers requiring men, and is doing very good work as an introductory bureau.

There is always an up-to-date list of vacancies and of application for employment from discharged soldiers at the offices of the Central Committee, 83, Pall Mall, S.W.1.

At the present time there is a number of useful men requiring employment as chauffeurs, and they carry with them years of experience. Who wants a good chauffeur with a silver badge?

## The Remy Magneto-Generator.

In our last issue we showed a Harley-Davidson fitted with a Remy lighting outfit. The following brief description will doubtless be of interest to those who are not familiar with the workings of this system.

The Remy comprises a generator, three-cell battery, electric horn, head light, tail light, and sidecar lamp. The generator furnishes low-tension current for the lighting, horn, and storage battery, and also high-tension current for the ignition. It combines in the one unit the functions of both magneto and dynamo; consequently, no separate magneto is necessary. As soon as the engine is started the generator furnishes storage current for the battery as well as current for the ignition. Consequently the battery is always kept fully charged and ready for use when the machine is at standstill for lighting purposes.

Should the battery be run down from any cause whatever, such as inadvertently leaving on the switch, it is always possible to start the engine direct on the generator, when current will immediately be furnished alike for ignition, lighting, and horn; the battery will also commence to recharge as soon as the engine is started.

This system has proved most satisfactory in use, and has a distinct advantage in that the rider need not carry two separate units to furnish ignition and lighting current.

In submitting to the Editor articles, photographs, or drawings, contributors are asked to mention whether the illustrations are exclusive, and further to enclose a stamped addressed envelope for return of unaccepted contributions.

## THE RENOLD MOTOR CYCLE CHAIN

All our products are now used  
for War Purposes only.

We cannot supply private cus-  
tomers until after the war.

**HANS RENOLD, LTD.,  
DIDSBUY,  
MANCHESTER.**

Gives perfect  
protection in all  
kinds of weather.

Its advantages may be sum-  
marised as follows—

Will fit any sidecar—does not interfere with  
the steering—can be fitted easily and quickly—  
is entirely under the control of the passenger—  
can be adjusted to any angle—gives ample  
room and little wind resistance—vision is un-  
obstructed in whatever position placed, and  
can be instantly detached when not required.

We can give immediate delivery. Write us.

**Price £3:3:0**

**EASTING WIND SCREEN CO.**

## Dunhills

Ltd.,

359-361, Euston Rd.,  
London, N.W.

2, Conduit St., W

Manchester:  
90-92, Cross Street.

Glasgow:  
72, St. Vincent Street.

# MISCELLANEOUS ADVERTISEMENTS.

## PRICES.

**ADVERTISEMENTS** in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to **ILIFFE & SONS Ltd., and crossed** & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4.), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

## NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

## DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

## SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

## MOTOR CYCLES FOR SALE.

## IMPORTANT NOTICE.

Owing to the August Holidays, the issue of "The Motor Cycle" for August 9th must be closed for press earlier than usual. All copy and instructions for Miscellaneous Advertisements in that issue must, therefore, be in our hands not later than first post on Thursday, August 2nd.

## DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the production of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange, or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

## MOTOR CYCLES FOR SALE.

Enfield combination, P.H. lamp, hood, screen, Cowey speedometer, £89/10; also 1917 3 h.p. 2-speed twin, semi T.T. Model, with sporting Canoelet sidecar, 2 Lucas lamps, Stewart warner, full kit tools, machine only ridden 3 or 4 times, indistinguishable from new, £69/10.—Lamb's, below.

BRAND New Enfields actually here.—A 1917 6 h.p. 2-speed outfit, £115; also a 1917 2½ h.p. 2-speed 2-stroke, £44/2.—Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green, N. 'Phones: 169 Walthamstow, and 1956 Housney. [6001]

## Excelsior.

EXCELSIOR, magneto model, new and unused; £75.—Griffin's, 89, Gt. Portland St., W.1. [6016]

3½ h.p. Excelsior, B. and B., Druid forks, Bosch mag., good tyres and belt, semi bars; first cheque £13 secures.—F. Davy, 61, Edward St., Nelson, Lancs. [X3222]

1916 American Excelsior Combination, 3-speed, kick starter, dynamo lighting model, excellent condition; £65, or exchange.—136, Lavenham Rd., Wandsworth, S.W.18. [6172]

EXCELSIORS.—All models in stock; magneto model £75, electric lighting model £85; get a big X. You'll be satisfied.—Colmore Depot, Birmingham, Manchester, Liverpool, and Leicester. [X1462]

EXCELSIOR (American) Combination, 7-9 h.p., December, 1915, 3-speed, Binks 3-jet, new Dunlops, speedometer, numerous spares, £25 coach sidecar, child's seat, new condition throughout; £77/10; seen 10 to 6.—Russell, 27, Store St., W.C.1. [6077]

THE Good Old X, Standard Model, 7 h.p., 3-speed American Excelsior, £75; De Luxe models, with dynamo lighting outfit and speedometer, £85; special sidecars to match, £15 and £19; immediate delivery from stock of a limited number; every machine specially tuned and adjusted before delivery.—The Premier Motor Co., Aston Rd., Birmingham. [5949]

## F.N.

F.N., 7 h.p., and coachbuilt sidecar, in good condition; price £35.—64, Pages Walk, Bermondsey. [6336]

F.N. (late), 5-6 h.p., 4-cyl. mag., new tyres; £15/10.—Wandsworth Motor Exchange, Ebner St., Wandsworth (Town Station). [6102]

RIDER TROWARD'S, 31 and 78, High St., Hamp- stead.—F.N., 1913, 2½ h.p., 2-speed, clutch, 34 gns.; F.N., 5 h.p., 4-cyl., 12 gns. [5972]

## Grandex.

1916 2½ h.p. Grandex Lightweight, Precision, 2-speed and free. Bosch, new condition; £18/10.—65, Griffiths Rd., Wimbledon. [5947]

## Harley-Davidson.

1915 Harley-Davidson Combination, £59; 1916 ditto, £80.—Clapham Motors, King George St., Greenwich. [X3353]

1916 Harley-Davidson Combination, 7-9 h.p., 3-speed, electric light, horn, in good condition; £85.—Below.

1916 Harley-Davidson Combination, 7-9 h.p., 3-speed, lamps, horn, in very nice condition; £89.—Below.

1915 Harley-Davidson Combination, 7-9 h.p., 3-speed, lamps, horn, in splendid condition throughout; £65.—Elce and Co., 15-16, Bishopsgate Av., Camomile St., E.C. [0491]

HARLEY-DAVIDSON 118 Combination, bought new 1916, fully equipped; £75.—D. O. Lamb, 151, High St., Walthamstow. [6208]

COLMORE Depot, Birmingham, Manchester, Liverpool, Leicester, for immediate delivery of all models of Harley-Davidsons, and spare parts. [0802]

1915 Harley-Davidson Combination, in tip-top condition, mag. model, lamps, etc., small mileage; £70.—M., 14, Gladsmuir Rd., Highgate, N.19. [6206]

1916 Harley-Davidson Combination, magneto model, accessories, perfect condition; bargain, 75 gns.—Smith, 15, Rupert St., Leicester Sq., London. [6091]

HARLEY-DAVIDSON 1915 Combination, done 3,000 miles, Bosch, car lighting set, excellent condition, spares; £65.—Newman, 81, Walhouse St., Walsall. [X3306]

HARLEY-DAVIDSON, 1915, 7-9 h.p., 3-speed combination, splendid condition, tyres new, all accessories; £60—4, Criterion Buildings, Windows Bridge, Thames Ditton. [6025]

## MOTOR CYCLES FOR SALE.

## Harley-Davidson.

**HARLEY-DAVIDSON**, 1917 electric model, hardly used; sell £119, or exchange Douglas 2½ h.p. and cash; letters only.—G.H.E., 38, Chambers Lane, Willesden Green, London. [X3308]

**HARLEY-DAVIDSON** (late 1915), little used combination, hood, screen, spare tyres, chains, speedometer, petrol, consider late Douglas part; £68 cash.—20, Stanhope Rd., Sidcup, Kent. [6191]

**HARLEY-DAVIDSON**, 1916, electric model, underslung Bramble sidcar, same colour, hood and screen, tyres good, all spares and extras, condition perfect; £95.—Alpe, 54, Coval Rd., Mortlake. [X3255]

**RIDER TROWARD'S**, 31 and 78, High St., Hampstead.—1916 Harley-Davidson combination, dynamo lighting, 86 gns.; 1916 Harley-Davidson combination, standard, 82 gns.; 1915 Harley-Davidson combination, dynamo lighting, 69 gns.; 1915 Harley-Davidson combination, standard, 65 gns. [5974]

**HARLEY-DAVIDSON**, 17F, 7-9 h.p. Swan combination, hidden approximately 100 miles only, absolutely as new, £120; also 1915 7-9 h.p. J Model and sidcar, electric equipped, all tyres as new and unpunctured, a very creditable outfit, £75.—Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green, N. [6006]

## Henderson.

**HENDERSON**, 1913, 4-cyl. clutch, case sidcar, hood and screen, perfect condition; £50.—51, High Rd., East Finchley, London, N.2. [5998]

## Hobart.

**RIDER TROWARD'S**, 31 and 78, High St., Hampstead.—1916 Hobart, 2-speed, 2-stroke; 25 gns. [5975]

## Humber.

**HUMBER** Flat Twin Motor Cycles immediately from Colmore Depot, Birmingham. [0882]

**HUMBER**, 1912 model, 3½ h.p., 2-speed; £15.—Haines, 169, Lower Clapton Rd., N.E. [X3294]

**31 h.p.** Magneto Humber, spring forks, belt drive; £14/10.—Motor Exchange, Horton St., Halifax. [6117]

**1914 3½ h.p.** 3-speed Humber, lamp, etc.; £35: cash or easy terms.—R. E. Jones (Garages), Ltd., Swansea. [0863]

**RIDER TROWARD'S**, 31 and 78, High St., Hampstead.—Humber, 1913, 3½ h.p., 2-speed, clutch; 23 gns. [5973]

**HUMBER**, 3½ h.p., 2-speed, new tyres, engine and gears in perfect order; £13/10.—Howe, High St., Nuneaton. [X3194]

## Indian.

**INDIAN**, 1915, 3½ h.p., 3-speed, splendid condition; £40.—127, Clapham Park Rd., S.W. [5912]

**INDIAN**, 7-9 h.p., 2-speed, with Montgomery sidcar, splendid condition; £39.—31, Trafalgar Rd., Wigan. [X2927]

**1912 4 h.p.** Single-cyl. Indian, 2 speeds, free engine; £25/10.—Motor Exchange, Horton St., Halifax. [6118]

**7-9 h.p.** Indian, 1912, clutch model, 2 lamps, kick starter; £28.—10, Norwood Crescent, Southampton. [X3272]

**INDIAN**, 6 h.p., 1914, clutch model, going Overseas, must sell; £27, no offers.—Box L4, 156, c/o The Motor Cycle. [6058]

**INDIAN**, 7-9 h.p., 2-speed, spring frame, late model, first-class condition; £54.—Haines, 169, Lower Clapton Rd., N.E. [X3291]

**7-9 h.p.** Indian, 1916 clutch model, in condition like new, complete with all accessories; £55.—Wanchope's, 9, Shoe Lane, London. [6075]

**INDIAN**, late 1915, 7-9 h.p., 3-speed, kick-start, Indian Heedee sidcar, in grand condition; 55 gns.—785, High Rd., Leytonstone. [6133]

**INDIAN**, 1915, 7-9 h.p., standard combination, spring frame, electric equipment, lovely turnout; £65.—51, Mapletorpe Rd., Thornton Heath, S.E. [6196]

**INDIAN**, 1915, 7-9 h.p., in nice condition, £42; Indian, 1915, 5 h.p., equals new, 3 speeds, £45.—Percy and Co., 337, Euston Rd., London. [5865]

**INDIAN**, 1915, 7 h.p. De Luxe Model, spring frame, countershaft 3-speed, kick starter, electric lamps and horn, coachbuilt sidcar, combination new August, 1915, and had little use, perfect condition; £70.—The Premier Motor Co., Astor Rd., Birmingham. [5950]

**1914 Indian** Spring Frame Combination, 7 h.p., 2-speed, clutch, kick, speedometer, electrically equipped, 30 gns. Canoelet sidcar, new spare tyre, tools, beautiful turnout, unused for 18 months, only done 4,800 miles; £50, offers.—55, Bulstrode Rd., Honeypot. [6080]

**RIDER TROWARD'S**, 31 and 78, High St., Hampstead.—1915 Indian, 7-9 h.p., 3-speed, clutch, kick start, electric lighting, 49 gns.; 1915 T.T. 7-9 h.p. clutch model Indian, 39 gns.; 1914 7-9 h.p. Indian, 2-speed, clutch, spring frame, 35 gns.; 1911 Indian, 5 h.p. twin, 17 gns. [5976]

**INDIAN**, 1915-16, 5 h.p., 3-speed combination, with accessories, tyres unpunctured, enamel uns scratched, semi T.T. bars, very pleasing outfit, £68/10; also 1915-16 7-9 h.p. clutch model, T.T. bars, disc wheels with lamps, horn, and large exhaust whistle, condition equal to new, hidden approximately 1,500 miles, £55.—Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green. [6007]

# Forwards fail?—Never!

They are so scientifically correct in construction that failure is impossible. The most destructive conditions only go to prove how true this is of Forward Fasteners.

## MOTOR CYCLES FOR SALE.

## Ivy.

**IVY**, 1915, 2-stroke, in fine order; £18/10.—The W. Hall Garage, Walsall. [X30]

**IVY**, 2-stroke, 2½ h.p., 1915, good tyres, fully equipped as new throughout; £23.—Advertiser, 156, Portland St., W.1. [39]

## James.

**41 h.p.** James, 3-speed clutch, Dunlops, good condition; £30.—Hutton, Kineton, Warwick. [X30]

**COLMORE** Depot, 261, Deansgate, Manchester, in stock complete range of James motor cycles. [0]

**JAMES**, 1915, 2-stroke, 2-speed countershaft, lamp, etc., with 4 gallons petrol; £25.—194, Storky Rd., S.W. [60]

**1917 James** 2-stroke, 2 speeds, in absolute new condition, done 200-miles, complete; £28.—Effingham Sq., Rotherham. [X30]

**JAMES** 1916 Combination, 4½ h.p., practically as done 250 miles; £70; appointment.—Elsie V. Lansdowne Av., Leigh-on-Sea. [61]

**JAMES** 1914 Combination, 4½ h.p., 3-speed coach, clutch, kick start, excellent condition; 1—Griffin's, 89, Gt. Portland St., W.1. [61]

**1913 James**, waterproof Bosch, chain drive, coach shaft 2-speed gear, and coach sidcar, body in new; £36/10.—Motor Exchange, Horton St., Halifax. [6]

**JAMES**, 1914, 4½ h.p. (S.A. 3-speed hub), Camo sidcar, coachbuilt, screen, and lamps; owner away 2½ years; £50.—Box 1,093, c/o The Motor Cycle. [X30]

**JAMES**, 4½ h.p., solo, purchased new December, 1917, run 1,000 miles, practically new condition, 3-speed clutch, kick starter; £55.—Mack, 11, Esplanade, L. tort. [5]

**JAMES** Actually on premises.—1917 3½ h.p. twin speed solo, £69/10; also 1917 4½ h.p. No. 1 speed combination, £87/2.—Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green, N. [6]

**FOR** Sale, motor bicycle and sidcar, James combination, 4½ h.p., condition as new, special silver storm apron, etc.; £65, with all accessories.—Write appointment, 284, Sales Advertising Offices, Fleet E.C.4. [6]

**RIDER TROWARD'S**, 31 and 78, High St., Hampstead.—James, new models in stock, 4½ h.p. single, 3-speed, £69/10; 3½ h.p. twin, 3-speed, £69/10; 1915 3½ h.p. twin James combination, 52 gns.; 4½ h.p. James, 3-speed, 37 gns. [6]

## J.A.P.

**IMPERIAL J.A.P.**, 1916, 2½ h.p., 2 speeds, new condition throughout; 29 gns.—Stevens, Tork. York. [X30]

**6 h.p.** J.A.P. Rex-Jap, complete with coachbuilt car, 2-speed gear, spring seat, in splendid condition; £60.—Turpin, 29, Preston Rd., Brighton. [6]

**1915 4 h.p.** J.A.P., overhead valves, T.T. bars, Palmer tyres, horn, lamp, and accessories, Dunlop belt; too fast for owner; £25, or exchange lightweight.—45, Bow Common Lane, E. [6]

## Lea-Francis.

**LEA-FRANCIS** 1916 Combination, twin, 3-4 countershaft, Bosch, lamps, Watford speedometer trial; £55.—Norman, 26, All Saint's Green, W.1. [X30]

## Lugton.

**LUGTON**, 3½ h.p., B.S.A. 2-speed, in new condition only used a few times; £30, or bargain.—Haines, 169, Lower Clapton Rd., N.E. [X30]

## Levis.

**LEVIS**, 2½ h.p., new condition, 1916; price £27.—High St., Rugby. [X30]

**1915 Levis**, accessories, almost new; £20.—Swan, Drayton, Middlesex. [X30]

**LEVIS**, 2 speeds, in real good condition; £2.—Percy and Co., 337, Euston Rd., London. [6]

**COLMORE** Depots, Birmingham and Leicester, delivery of all models of Levis motor cycles in stock. [0]

**LEVIS** 1917 Popular, latest model, brand new; —Wilkins, Simpson, and Co., 11, Hammer Rd., London. [X30]

**1915 Levis** 2-stroke, good condition, new mechanical horn; £17/10.—436, White Rd., Thornton Heath. [6]

**LEVIS**, 1915, 2-speed, 2½ h.p., good condition, £17 with cash for 3½ h.p. with 3-speed gear, Cleveland Rd., Hornsey, N.8. [6]

**LEVIS**, 1917, 2½ h.p., 2-speed Model E, £47/10; 1917 2½ h.p. No. 1 Model, single-speed, £3.—Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green, N. [6]

**LEVIS**, 2½ h.p., 1916, 2-stroke, large P. and H. lamp, generator, rear lamp, mechanical feeder cyclometer, condition as new throughout; Advertiser, 156, Gt. Portland St., W.1. [6]

**Petrol Permits.**

**M**OTOR cyclists by now are so well used to continuous thwacks from every quarter, and so impervious and docile have they become, that the majority will view the notice to holders of petrol licences with equanimity. Although it would be absurd to question the policy of this reviewing of all licences at the expiration of September, and of taking every precaution to conserve and stop all wastage of petrol, the Order comes heavily on those who, instead of hoarding month by month their supply, relied on being able to obtain at any future date the petrol on which they had paid their tax.

The notice says: "Full duty motor spirit licences of the *current* series are available for private motor cars during the period of May to October inclusive, and for private motor cycles during the period April to September."

The obvious inference is that after September no licence will be issued without strict enquiry as to the assertions respecting its use. Many current licences have been issued to people who made false claims, and had no legitimate reason for using petrol. Many business men have suffered extreme inconvenience through the small allotment granted them. The latter class have had full cause to grumble when they have seen petrol wasted on what were obviously pure pleasure rides.

The abuse levelled at the late Petrol Control Committee we do not think quite justifiable, although individuals may have full cause for complaint. The difficulty of the committee was in separating the genuine appeals from the spurious, and the new Controller will have precisely the same difficulty to contend with when it comes to issuing the new licences in October. We hope the small business man's claim will receive attention, for, as we have just stated, he appears to be the one who has suffered most in the allocation of petrol licences. It has not been unjust distribution, but stereotyped

methods of awards that have been the fault in the past, some owners being surprised at the committee's liberality and others at its meagre allowance.

**Other Fuels.**

Motorists have naturally turned their thoughts to the production of gases other than petrol vapour. We have heard of numerous experiments with acetylene, but these have not developed as the enthusiast would have liked. We have answered scores of letters from correspondents who ask, "Why cannot acetylene gas be used effectively in internal combustion engines?" Coal gas, of course, has been tried many times, and is being used successfully by car owners whose journeyings are in a prescribed area, bags holding half-compressed or uncompressed gas being used instead of heavy cylinders holding gas in a compressed state. In one case the space required for the gas bag debars its use on motor cycles, and in the other the great weight of the iron cylinders and the difficulty of charging and compressing would be the deterrent. The fact that coal gas would give less power is a drawback which would not alone prevent its use. Obviously, if it is not adaptable for general use on cars, motor cyclists need not look for developments in that quarter. Electricity, for the present, is impracticable, for obvious reasons; also, it would necessitate a different type of machine, as would the use of steam. There seems to be no hope whatever of a fuel being procurable in any quantity on which a tax has not to be paid. Alcohol produced from potatoes is spoken of as a probable solution, but obviously the product, if procurable—which, of course, it is not—would be liable to taxation.

It is easy to talk of the various fuels expected to be marketed after the war, but it does not solve the difficulties of the anxious rider who may have exceptionally justifiable reasons for using a motor cycle, but who cannot persuade the Petrol Controller to send him the welcome yellow folder.

## Another Throttle-controlled Pump.

### LUBRICATION IN PROPORTION TO SPEED AND LOAD.

**W**E illustrate on this page another very ingenious oil pump designed to supply the engine with oil varying in amount with the speed and throttle opening. Moreover, the supply of oil over the whole range can be set to suit different conditions. The inventor, Mr. T. G. Stuckfield, describes the pump as follows:

In view of the interest taken by *The Motor Cycle* and its readers in mechanical oil pumps, in which the supply of oil to the engine is controlled in relation to the load in addition to the speed, I am sending a drawing of such a pump, small in size, easily made, entirely self-contained, and requiring the minimum of alteration to the engine.

As can be seen from the drawing, the pump is attached to the outside of the timing gear cover by means of the three screws for which holes are drilled and tapped in the cover, and another hole is drilled through the bush of one of the 2 to 1 wheels, through which hole is passed the projecting end of the worm spindle, the flattened end of which engages in a slot in the end of the spindle of the timing wheel, thus driving the worm at half the speed of the engine.

This worm rotates the worm wheel, which is machined out of the solid bar complete with spindle and eccentric; the chamber containing the worm wheel and eccentric is closed by a screwed bush which acts as a bearing for the spindle. As the eccentric revolves it forces the plunger upward on its delivery stroke, acting on the anti-friction roller carried by the slotted circular enlarged end of the plunger; this enlarged end also forms a guide block working in the bored portion of the pump casing.

The pumping portion A works in a separate barrel B screwed into the casing, the joint being made by a washer under the shoulder as shown. This barrel is made of steel, hardened and ground in the bore.

Diagrams of a mechanical pump designed by T. G. Stuckfield. It is arranged to be attached to the outside of the timing gear cover.

The return or downward stroke of the plunger is made by means of a spring.

The ball valves and pipes are all carried by the T-shaped end of the pump casing; the delivery branch also carries two arms, which serve to carry the Bowden wire passing to the throttle valve from the throttle

Graph of oil consumption at various throttle openings.

lever, the wire from lever on handle-bar passing first through the spring box C, thence round the grooved double control wheel, thence through the adjuster D, and so on to the throttle valve.

#### Four Settings.

It will be obvious that as the throttle valve is opened these double wheels will be rotated through an arc equivalent to the amount of throttle valve opening, and when the lever on the handle-bar is moved to close the throttle valve, the spring contained in the box C will rotate the double wheels in the opposite direction.

Since the length of the arc through which the wheels are rotated is equivalent to the throttle valve opening, the angle will be less when the nipple engages the larger wheel in inverse proportion to the diameters of the two wheels. The double wheels are secured to a sleeve E concentric with the spindle; at the inside end of this sleeve two cams are formed, these cams having different contours and forming the stroke regulating mechanism of the pump, since they prevent the pump plunger coming back a distance, which varies as the cams are moved simultaneously with the movement of the throttle valve. When once set for any particular engine this need not be altered.

Changing the position of the nipple from notch to notch raises the mileage per quart 50%. This variation of mileage with each particular notch in use and with each variation of throttle opening is, perhaps, better shown by the graph on this page.

As was pointed out before, the pump is small, the overall dimensions of the body being  $3\frac{1}{2}$  in. high,  $2\frac{1}{2}$  in. over the arms, and  $1\frac{1}{2}$  in. wide over the Bowden wire arms; it is entirely self-contained, and requires no cover whatever, and the whole of the work, with the possible exception of the worm wheel teeth, can be done on a small screw-cutting lathe.

# Occasional Comments by "Ixion"

## Hitting a Dog.

I SAW a good man and true very completely knocked out by a very small dog last week. It happened much as usual. The motor cyclist was purring quietly along at about 18 m.p.h. down a main road on the outskirts of a large town. An Aberdeen terrier was proceeding sedately along the pavement in the wake of his mistress's skirts, musing on the chances of the cold beef turning out for supper when he spied a lady friend in company with a mongrel on the opposite pavement. He turned sharp right, accelerated to about 50 m.p.h., and caused the motor cyclist to hit the stone setts with his forehead about ten yards ahead. This casualty, let it be plainly stated, was of the avoidable order. I am no believer in the yarns of those riders who boast that they have motored since the year one and have never killed so much as a spring chicken. I have motored for a mileage which is rapidly approaching the quarter million mark, and I confess frankly that I have slaughtered many dogs, cats, chickens, and rabbits, and, without being in the least brutal or callous, I expect to slaughter many more.

## The Lesser and Greater Evils.

SO long as our roads form at once a public playground for birds and animals devoid of common-sense, and for human beings so young or so stupid as to be deficient in commonsense: and these same roads also serve as paths for comparatively rapid locomotion, collisions must be of frequent occurrence. Some day traffic objects of an irrational or careless character will be as scrupulously forced off our motorways as they are already excluded from our railroads, but that day is not yet. In the meantime, it is the duty of the motorist, whose wits are almost invariably the most quick-acting of the parties involved, to decide who shall bear the brunt of a dangerous position. The cardinal rule is that we must always sacrifice ourselves rather than injure other humans, and to our credit we uniformly obey this fundamental principle even when the blame rests wholly on the shoulders of the other party. There is probably not a motorist in the country who would not turn his machine into a stone wall rather than ram a fanatic at large, or drive over a drunkard asleep on the road at night. The second rule is that it is better to kill a domestic animal than to die oneself, or to risk serious injury oneself. After this preface I may proceed to expound the art of emerging scathless from a collision with a small animal.

## Hit it Full.

THE unfortunate rider above mentioned tried to dodge the murderous Aberdeen up to the very moment of impact. He steered this way and that, the frightened dog countering every movement with a fresh swerve. At the last he lost his head; his front wheel hit the animal's hindquarters, and I

am not at all sure that the rider had not let go his handle-bars when the collision occurred; at any rate, his wrists were not taut. His front wheel swung round at right angles to the rear wheel: the machine collapsed in a heap: the rider was flung yards over his handle-bar, and fell on his head in the road. There was no need for this. The instant he perceived his danger he should have tensed his wrists into steel cables and held his front wheel masterfully and irresistibly true in the line along which he was advancing; the dog should have been left to attempt the dodging, and would probably have done it successfully, for if dogs are not logical, they have quick instincts and profound fears. But, supposing the dog had held to its course, precisely, at right angles to the motor cycle's track, the motor cyclist would have gone clean over it, and in all probability neither of them would have been seriously hurt. The motor cyclist would merely have had to regain control after a bump, and possibly a wobble. The dog would not have been cut or wounded, though its back might have been broken. As it was, the rider was seriously injured, and the dog had to be destroyed.

## The Art of Colliding.

IN brief, then, quite large animals, even retrievers, can be safely rammed in emergencies, provided the steering wheel is held dead on its course by strong wrists. It is a big dog which weighs 50 lb. or stands more than eighteen inches high. The cycle and rider represent a mass of perhaps 500 lb. striking at right angles at perhaps 20 m.p.h. The first result of the impact is to throw the animal over on its side, when the height of the obstacle to be surmounted shrinks in a thousandth of a second from perhaps 18 in. to 6 in. Over this the machine will roll without danger if the wheel is held on its course firmly: and even poor doggie will often be only temporarily the worse. If any steering at all be permissible, the rider should aim at the middle of poor doggie's back. But it is probably sounder practice to concentrate on steering dead straight ahead.

## Bending Footrests Down.

I RECENTLY referred to the fact that on some machines the footrests are apt to foul the ground when the rider is cornering at speed. A Yorkshire rider forwards a T.T. tip which he has found useful in his pleasure riding. There are two methods of dealing with the trouble, one of which is to bend the outer tips of the rests up. It helps to keep the feet on the rests, and gives a purchase for the boot, and a slight upward turn will prevent the fouling, which is never more than slight. If this plan be objected to on the ground that the right and left hand rests are usually assembled by threading on a single spindle, the best method is to shorten the rests by an inch or so, which makes an astonishing margin between fouling and not fouling the road.

# MORGAN

Descending from Buttermere Hause on the way to Honister Crag.

## THE FIRST CYCLE CAR TO CLIMB HONISTER PASS FROM BUTTERMERE.

BY GEORGE D. ABRAHAM.

(Author of "The Complete Mountaineer," "Motor Ways in Lakeland," "Mountain Adventures at Home and Abroad," etc., etc.)

NOT long ago the story in *The Light Car* of a remarkable record ascent of Honister Pass from both sides by a little Swift coupé, standard in every respect, roused considerable attention. Several attempted the same performance, but with scanty success. Gruff old Honister handled all very roughly, until at last a David arose in the form of a little Morgan. In the writer's opinion, this seemed scarcely a likely conqueror, for friends who in pre-war days owned these mounts had never seemed keen on trying their machines on real motor-mountaineering. Thus an invitation to join in an attack on Honister from Buttermere was accepted gladly.

A young Danish enthusiast, Mr. Neils Svansø, was the owner of the Morgan. His stories of hill conquests in other districts made one almost apologise for having nothing better than Honister Pass close at hand. The quiet air of the lower dales echoed with the names of Litton Slack, Cowdale, and innumerable other "pimples" as we sped westward from Keswick, bound for Buttermere by the Vale of Newlands and Buttermere Hause. There was no mistaking the extreme efficiency of the Grand Prix model. With three lusty passengers and a very important member of the party in the form of a heavy camera

outfit aboard, it was no light undertaking to tackle at the outset one of the toughest mountain roads in Cumberland.

### The Charms of a Bob-sleigh.

The little machine carried us up to the heights and slid us down to the depths of the dales with fascinating ease and smoothness. Those wonderful downhill glides on the low-seated outfit recalled the charms of a bob-sleigh or toboggan run, and instinctively one swung to the balance on the curves.

The hardened "Morganites" were amused at the tendency, and with the crush aboard their places on the machine were sometimes in jeopardy. Apparently there was no need to "swing" with the Morgan, even on the sharpest curves taken swiftly. But as we sped down from the sunny heights into the larchy shades under the huge towering mass of Causey Pike, the sight of the Devil's Elbow recalled memories of a certain rashly-driven Morgan which capsized recently on the notorious hairpin. The writer warily suggested that an interesting photograph should be taken, and from the solid mountain side it was a revelation to see the present machine and driver rush the tricky hill so splendidly. With the two standard gears fitted

**Mountaineering on a Morgan.**

— $4\frac{1}{2}$  to 1 and  $7\frac{3}{4}$  to 1—this was no mean performance. The writer's want of confidence totally disappeared.

**In the Vale of Buttermere.**

Then with all aboard there came the delightful dash skywards 'midst the bracken heights, until the forbidding scarp of Newlands Hause rose ahead. There was now no photographic excuse. The little machine fairly prang at the opposing slope, leaping, bumping, and skidding on the treacherous shale, but always under sure and skilful hold.

Surely never was the pass seen so speedily climbed; the summit seemed no sooner in view than it was attained. After another photographic halt, we were soon sliding carefully down into the Vale of Buttermere, amidst all the grandeur of rugged mountains and beauty of blue lakes set in an emerald underworld. It was good to have companions who realised the unique and varied beauty of this corner of Lakeland, so unlike an unappreciative Lancashire tourist at Windermere, who said bluntly, "When tha's seen half a mile on't tha's seen t'lot."

**On Honister Pass.**

Then came the engrossing run along the lake shore, with Honister Crag looming ahead just as grandly as in the peaceful times when throngs of enthusiasts now crowding far distant trenches came to try their luck and pluck on the most famous of English hills. Unlike those days, there now arose no strident note from behind to hurry us to speedier ravel mountainwards. Yet once the actual climbing

began there was no holding back the machine. The lower part of the pass was tackled with remarkable ease, and the writer, now alone and afoot, walked up the slope rather doubting whether Honister would retain its reputation in the face of the dashing Morgan. They were out of sight, but far overhead the noise of the lusty engine echoed persistently in the huge

crag. Surely the fearsome gradient of Hill Step—the crux of the climb—could not be ascended at the first attempt.

The noise continued until the view of the upper part of the pass was revealed, and there was a certain satisfaction in seeing far above the mid-way bridge a tiny black speck almost hidden in blue smoke roaring furiously but absolutely still. The Morgan had stuck on a steep, stony, 1 in  $3\frac{1}{2}$

gradient about fifty yards below Hill Step. Even this was a very astonishing climb considering the fact that no rope or chain had been used on the driving wheel. The special, sturdy, Stepney road-grip tyre had behaved excellently, and now its grip was augmented by a rope bound round the driving wheel. An excellent restart was made despite the extreme steepness, but unfortunately the unsuitability of the Morgan driving wheel for any non-skid attachment was quickly revealed. There was a crash from below, and a "dash" from the driver—the low gear driving chain had broken on account of its entanglement with the rope. Luckily a spare chain was carried.

**"Over the Top."**

Despite an annoying surfeit of links, as well as a lack of proper tools, the new part was made the correct length to be eventually fitted, and the grimy

(Top) The first cycle car over the crest of Hill Top, above the most difficult bit of the pass. The road is seen winding valleywards over 500 feet below.

(Bottom) A tough struggle up the 1 in  $3\frac{1}{2}$  gradient below Hill Step, the crux of the climb. Observe the rough sliding rock-strewn surface.

### Mountaineering on a Morgan.—

operators restored to the semblance of white men once more. Then ensued the final struggle which made the driver forget all other hills. Honister upheld its reputation. Machine and driver stuck to their work

By the shore of Buttermere, with Honister Crag looming grandly in the distance on the left.

bravely, and despite the wildly whirling driving wheel, which even the weight of two extra passengers failed to stay from slipping perpetually, the rugged slope was gradually overcome. Loose stones were flung all round, and it was positively dangerous to approach the tail of the machine.

There was an ominous smell of burning rubber, and when the crest of Hill Step was topped we found the corrugations of the driving tyre had disappeared. Still, the driver was delighted; in his opinion the success was worth many new tyres. On the upper part there was much jubilation and photography, but the photographer of the party discovered a serious trouble. A valuable lens had been left behind somewhere earlier in the day. Thus instead of finishing the day's run on the eastward side of the pass to Borrowdale, the backward journey was made by the morning's route.

The return to the hotel gave momentary satisfaction to those who had previously prophesied our failure on

Honister, but there were no sceptics, and had there been, the camera held proof of the successful achievement. That wonderful homeward bound rush up Buttermere House was certainly well worth the *détour*, the more so as the lost property was safely recovered from the top of a wall where it had lain all day. The Morgan had proved its powers and efficiency in astonishing fashion, but those who repeat the adventure would do well to use the lowest gear available, viz., 11½ to 1. With the capital independent chain system for each gear, this could be easily done without spoiling the fast long-distance running of the

In the shadow of Honister Crag. The Morgan swinging round the first corner below Hill Step.

machine. On gradients approaching 1 in 3 the carburettor was so placed that it failed to provide full power to the excellent engine, but with a good supply of petrol in the tank this drawback would scarcely occur. There was no overheating, and the writer looks forward with pleasure to further exciting hill conquests on the Grand Prix Morgan when normal times return.

### PETROL FOR MINERS.

A NUMBER of applicants for assistance in obtaining petrol licences have been received by the Auto Cycle Union from miners and other workers at coal mines. They were originally referred to the Ministry of Munitions for the necessary recommendation, but no sympathy could be obtained from that department. The Union, therefore, approached the Controller of Coal Mines at the Board of Trade,

who promptly recognised the advisability of helping those colliers who, although owning motor cycles, are now compelled, owing to their being unable to secure supplies of petrol, to walk long distances to the coal mines. The necessary particulars of each individual case have to be furnished on a form which can be had on application to the Secretary, Auto Cycle Union, 83 Pall Mall, S.W.1.

## MILITARY NOTES.

MOTOR CYCLISTS OF THE TRANSPORT SECTION.

A group of A.S.C., M.T., men who have been out in France since 1914. Reading from left to right: Pte. Dodsforth, Cpl. Carter, Cpl. Every, Sgt. Gibbens, Ptes. Naylor, Evans, Lunn, Roberts, Pye, Croft, Wood, and Johnson.

## FLIGHT-SERGEANT SIDNEY GEORGE.

WE have perused an interesting communication received from Sidney George, the well-known Indian rider, and give hereunder a few extracts: "No doubt you would be interested if I gave you a description of the motor cycle repair shop of which I have charge. On October 16th an old warehouse was lent out to me as the motor cycle shop was to run. I can tell you, it did not look very encouraging, but with the aid of carpenters and one or two fatigue parties we worked wonders, and now I have a shop of which I am very proud. I wish I could get some photographs, but, of course, it is not possible at present. The

Flight-Sgt. Sidney George, R.F.C.

warehouse that was is partitioned off into shops, and these consist of the dismantling shop, where all the P. and M.'s are pulled down; the engine shop, to which the engines and gears are sent; the frame shop, where frames and forks are brazed; the wheel-builders' shop, and shops where tanks, chain cases, and mudguards are handled by the tinsmiths, so that each part goes to the men told off to repair it. The largest portion is kept for the erectors, where four men are busy every day. A shop has been built for the fitters, where every part is re-assembled, and two ovens kept going all day long. I have twenty-four men, who are kept up to their work to turn out a complete overhaul a week, and up to date the job number is 230, that is, 200 complete overhauls since October. A record is kept of all machines—what parts are used, who repaired the units, who selected the motor cycle, and how it performed on test—so you see the work is not shirked in any way. At present there are over ninety machines waiting for overhaul. An Austin two-cylinder set supplies the light, and power for the lathe,

drilling machines, emery wheels, etc. I have had the supervision and testing of all the machines overhauled in this shop. And speaking of tyres, I have found the Kempshall a really marvellous tyre for reliability and stability. Despite the terrible roads, they stick it and stand the most severe tests. I have one competition rider in my shop—Neville Hall, of O.K. fame—and wish I had a few more like him. The P. and M. is a very nice machine for the job. But what would I give for a roar on my old 7 h.p. Indian, and what a blessing an Indian spring frame would be on these roads!" Sidney George is now a flight-sergeant in the R.F.C., having been promoted from first air mechanic.

□ □ □

## RACING WITH VICKERS-CLYNOS.

AS a change from the ordinary routine of training, races with Vickers-Clyno outfits were arranged recently at a training centre in the Midlands, and caused a good deal of excitement and

The winning team of Vickers-Clynos in a race which took place recently at one of the large Midland camps.

interest. Sgt. Harlow, of the M.G.C. (motors), in writing about the event, says a distance of 250 yards had to be covered and the guns placed in action on a given target which was mounted ten yards in

front of the cycles. Six teams competed, the race being won by the team shown riding past the huts led by an officer mounted on a Douglas.

□ □ □

## OVER-AGE MEN FOR HOME DEFENCE.

LORD FRENCH, speaking at Ilford recently, appealed to men physically fit and over the military age to join the "A" section of the Volunteers for home defence. The intention of the Government in re-establishing the Volunteers, he said, and the use to which it was intended to put them, were simply to provide efficient home defence in case of invasion; and, inasmuch as all men of military age were required at the Front, it was expected that this duty of home defence would be undertaken by men who were over that age, but were still sound and fit in body and mind to take their share in this work. They were not asked to go out of the country in any circumstances whatever. They were not even asked to leave their

homes or the districts in which they lived. They were asked only to enrol for this service and, to spare a few of their leisure hours in preparing and fitting themselves as efficiently as possible. The men who could be absolutely counted upon for the defence of this country were these "A" men, and one could make no efficient plan for the defence of this country in case of invasion unless one could count with certainty upon the number available at the moment. He wanted them to do their utmost to make every available

man join the Volunteers, and make that addition of strength really effective. This could be done by inducing all men who were in the "D" class to take service as "A" men.

**D**URING the past few months much has been written on the *pros* and *cons* of the four-cylinder motor cycle, and the purpose of this article is to discuss a few of the leading features in the design of the engine, particularly regarding weight, as there appears to be a prevalent but erroneous idea that the type is excessively heavy. A comparison with aeroplane practice will show that within certain limits a multiplication of cylinders leads to a reduction in weight. Paradoxical though it may seem, the eight-cylinder engine can be made as light as the four-cylinder of an equal capacity, though that question does not enter into the sphere of motor cycling. Trials carried out by the Automobile Club of France and other bodies show that an air-cooled aeroplane motor can be built of a weight under 5 lb. per brake horse-power, a figure which, when compared with motor cycle engines, shows that the question of serious weight reduction has scarcely ever been considered.

#### Piston Pressure and Inertia.

Two fundamental requirements of a smooth and flexible engine are perfect firing and running balance, and both are unobtainable with a single-cylinder, as the power stroke occurs only every other revolution, and it is impossible to balance the reciprocating parts against the revolving portions of the mechanism. With a four-cylinder engine the explosions occur at equal intervals, twice every revolution, and the moving parts are all balanced against each other. A further and important factor arising from dividing up the work among a number of small units is the reduction of stress in the working parts with consequent possibilities in the way of reduction of weight and wear of bearing surfaces. The internal stresses in an engine arise from two things: the explosion pressure and the inertia of the moving parts. The explosion pressures are reduced proportionately to the area of the pistons, which varies as the square of the cylinder diameters. For example, in the case of the four-cylinder F.N. and an 85 mm. x 88 mm. single-cylinder engine, this is 52.5 mm. x 52.5 mm. to 85 mm. x 85 mm. or 1 to 2.6. Taking the explosion pressure to be 300 lb. per square inch, this amounts to 1,010 lb. and 2,640 lb. on the two pistons under consideration.

The inertia pressure may be explained as follows: As the piston comes to the top or bottom of its stroke it slows up, stops instantaneously, and starts moving again in the opposite direction. The resistance of the

## Design of Four-cylinder Motor Cycle Engines.

Points in which the Four-cylinder Engine  
is Superior to Common Practice.

moving parts to this change in velocity and direction of motion is said to be due to their inertia, and results in a pressure which reacts on the bearings and depends on the weight and rate of acceleration and retardation. At high speeds the pressures so caused may even exceed those due to the explosion, and form an important factor in engine design.

#### Weight per Horse-power.

The modern single-cylinder motor cycle engine has the greatest weight per horse-power of any type used for vehicle propulsion, due chiefly to the large and heavy flywheels required. When placed inside the crank case they average about 8½ in. diameter and weigh 25 lb. to 30 lb. per pair, while the miniature four-cylinder of 500 c.c., owing to its perfect balance and even firing, does not require more than 10 lb., and this can include the clutch. This is also the correct location for the latter, as the speed being highest the pressure and surface required is least, so that it can be made smaller and lighter than if placed anywhere else in the transmission system. What would be thought of the car designer who incorporated the clutch in the back axle, as is so often done on a motor cycle?

We will continue the discussion of the weight question by taking comparisons between a well-known and representative 500 c.c. single-cylinder engine and the 5 h.p. F.N., as the latter is the only successful four-cylinder of this size. Regarding the reciprocating parts. The usual 85 mm. piston weighs, complete with rings and gudgeon pin, 1 lb. 6 oz. to 1 lb. 12 oz., and the connecting rod 14 oz. to 1½ lb. This gives an average weight of piston and connecting rod of 2 lb. 10 oz., which, it should be noted, cannot be perfectly balanced. The four 52½ mm. diameter pistons of the F.N. have a total weight of 2 lb. 6 oz., and connecting rods 1 lb. 4 oz., the reciprocating weight per cylinder thus being 15½ oz. These masses are perfectly balanced, and the stresses due to the inertia and explosion are largely reduced.

The limitations of crank case width, etc., reduce the bearing surfaces of the conventional single or twin to absurd proportions, while on a miniature four-cylinder they can be made of the same generous dimensions as on a high-class car. This means lessened pressure per square inch of bearing surface, with better lubrication and longer life. The previously referred to limitations make the usual motor cycle valve gear a difficult matter to design and construct.

**Design of Four-cylinder Motor Cycle Engines.—**

The valves have to be large and the springs strong, while the operating mechanism must be packed into a case an inch or so wide, thus involving narrow gear wheels and tiny bearings, which are difficult to lubricate. On the other hand, the valve gear of a car engine is almost uniformly satisfactory, largely due to its being in the crank case, ensuring a sufficiency of oil, with accommodation for ample bearing surfaces. The same advantages apply to the miniature four-cylinder, while the small valves and light springs reduce the stresses in all parts.

The four cylinders of an F.N. total 12 lb., and an 85 x 88 cylinder averages 8 lb. An important point in connection with air cooling is that the smaller the cylinder the easier it is to keep cool. This is because the surface of a cylinder is proportionate to its diameter, while its volume increases as the square of its diameter, so that the volume increases at a greater rate than the cooling surface. Better cooling permits the use of a higher compression, while a thinner oil can be employed with consequent reduced carbonisation and friction. With inside flywheels there is an appreciable loss arising from the churning up of the oil between the flywheels and the crank case, and it is an open question whether this does not more than counterbalance the loss due to the extra bearing surfaces of an equivalent four-cylinder.

The F.N. crank case in cast iron weighs 17 lb., but if made in aluminium could easily be reduced to about 11 lb., which does not compare unfavourably with the usual type having inside flywheels. The weight of the complete single-cylinder engine with magneto, silencer, and belt pulley is 84 lb., and the four-cylinder engine with cast iron crank case and including the clutch comes out at 72 lb.

Take the case of larger engines up to 1,000 c.c. The ordinary V twin has a lower weight per horsepower than the single, as the flywheel weight is about

the same with the addition of an extra cylinder, piston, and valve gear, but even then a four-cylinder engine offers greater scope for weight cutting.

**Balance and Torque.**

Compared with the flat twin, there is not much to choose on the score of balance, torque, or weight, but with two or three noteworthy exceptions the type does not appear to have become popular, due probably to its length and the difficulty of designing a really suitable frame. Actually, with a ball bearing crankshaft and the magneto placed alongside the engine, a four-cylinder can be built very little longer than the first two types mentioned, and certainly shorter than a flat twin, with the advantage that it lends itself exceedingly well to good frame design. The down tube of the frame can be divided and made double, the engine resting on bearers between the two parallel tubes, giving a very stiff construction, which does not depend on the crank case for obtaining its rigidity, as is usually done, this being another instance of car practice applied to motor cycles.

One essential of success is continuous and automatic lubrication, but in the light of modern knowledge this is not difficult, and could be done on car lines with fixed troughs under the connecting rods, fed by a small gear pump submerged in the oil in the lower half of the crank case. Owing to its being placed longitudinally in the frame and the relatively short stroke, limitations in width and height do not seriously affect the engine, which is as adaptable to scientific design and construction as the best car engines, and with good materials there is no reason why it should not be as reliable.

This article does not do more than touch on the fringe of a very interesting subject, and is only intended to show that the four-cylinder motor cycle engine is not such a difficult problem as it appears at first sight.

E.C.

**MOTOR VOLUNTEERS.**

Motor cyclists are performing useful work in conveying men from the Front from one London station to another at night when ordinary vehicles are unobtainable. The corps shown is attached to No. 1 Squadron, County of Middlesex Volunteer Transport Corps. There are still vacancies for a number of sidecarists, who should apply to Mr. W. E. Boyce, 331, Archway Road, Highgate, N.6.

## SPECIAL FEATURES

MOUNTAINEERING ON A MORGAN.  
DESIGN OF FOUR-CYLINDER ENGINES. MECHANICS FOR THE MOTOR CYCLIST.

## TIME TO LIGHT LAMPS

## SUMMER TIME.

Aug.	9th	...	...	9.4	p.m.
"	11th	...	...	9.0	"
"	13th	...	...	8.57	"
"	15th	...	...	8.52	"

## Our Aim.

Robert Burns was a great poet, and he has made Scotland dearer to the memory of the exiled Scot. In these days when so many are exiled we hope *The Motor Cycle* will bring fragrant whiffs of by-trodden paths. May we be the Bobby Burns of the motor cyclist—such is our aim.

## Devonshire Roads.

Many of the country roads in the tourists' routes of North Devon are distinctly rough and pot-hole, but one is repaid by finding the many beautiful villages free at last from the scourge of the day tripper. There are, of course, no pleasure steamers running this year, and most of the public services are stopped, so that the villages are suffering from a shortage of visitors.

## Conserving Petrol Supplies.

The ways of the Petrol Control Board are weird and strange. When, on July 31st, it became known that there was no object in trying to make a three months' licence spin out over six months, there was a general rush to the garages to obtain July's supply. But, hi-presto! there was no petrol to be bought, and no more to be supplied to the large dealers for a day or two. There are other ways of conserving the petrol supplies beside licences.

## On the Perverseness of Babies.

Two-strokes are kittle cattle. The expert is sometimes puzzled by them, but the majority of riders take them as they go without attempting to analyse the various inequalities of running that frequently manifest themselves. When a machine, which previously ran ninety miles to the gallon of petrol, suddenly drops to sixty over the same course, there is usually a good reason for such behaviour, but it is not easily found, as was the case with a reader's two-stroke recently. It happened that the machine was put in the garage and not touched after its petrol devouring display. A few days later it was taken out again and accomplished the same journey at ninety miles to the gallon and pulling infinitely better. Who can deny the perverseness of the babies when such a thing happens? Would that leaving the machine in the garage for a few days would always work such wonders!

## Overseas Machines.

Norton Motors, Ltd., whose new military model is particularly adapted to Overseas requirements, inform us that these machines are to be known as the Empire model, instead of the Colonial model as hitherto.

## Another American Record.

Clelo F. Bruschi has beaten Lt. E. L. Hoffman's twenty-four-hour sidecar record of 963 miles by covering 1,000 miles in 22h. Bruschi, mounted on a Harley-Davidson outfit, went over practically the same course as Hoffman, and abandoned the run with two hours to go on reaching the 1,000 miles mark.

## Sea Fishing.

Scores of motor cyclists are probably looking forward to spending a few days sea fishing this month, and for the benefit of such we would state that very stringent measures have been taken to limit pleasure boating of any kind. No seaman under 60 years of age is now permitted to undertake pleasure cruises, for which special permits are required.

## Noisy Valves.

The clatter of overhead valves on many highly efficient twin-cylinder engines is really beyond all reason, and a delightful machine may be spoilt by the hideous din it makes. If we are to have overhead valves on solo mounts—and undoubtedly we are—then some attempt must be made towards silencing the mechanism, or many riders will fight shy of this type of engine.

## A Motor Cycle Stolen.

Sgt. Frank Offer, C Company, 3rd Training Battalion, informs us that his 2½ h.p. New Imperial J.A.P. machine has been stolen. The engine number is A2318, the frame number is A5137, and the registration number is LR2362.

## Munition Workers' Motor Cycle Repairs.

At one or two South London motor cycle depots the repair and tuning of motor cycles owned and used daily by munition workers are especially undertaken, few having the necessary time to attend to their own machines. Light weights, and the Douglas in particular appear to be the favourite mounts, and most riders carry their day's meals in a carrier bag. Some of the machines cover twelve to twenty miles a day, and most use substitutes. One Enfield had a substitute carburetter and small petrol tank for starting.

## Old Petrol Permits.

The new restrictions demanding the return of early licences, though, of course, quite just, are apt to hit those who have made real attempts to economise hardest of all. Many riders have avoided buying petrol until they actually required it, with the result that these worthies now find themselves with old licences on their hands, and with precious little chance of obtaining new ones, while others have obtained their petrol as it fell due and stored it. In this world it always pays to keep up-to-date.

Chief-Gnr. Kenneth R. Waite, who was wounded in the Dardanelles, delivering a recruiting speech to employees outside the main entrance of the Harley-Davidson motor cycle factory at Milwaukee. Waite, who is recuperating from his wounds, is using his time to good advantage by placing himself at the disposal of the United States Army and Navy.

**Competition Rider Married.**

Kenneth V. Chidley, who successfully rode a flat twin Brough in competition in 1914, was married on August 4th to Miss Mahel Gibson. The best man was P.O. S. P. Brown, R.N.A.S., who rode a Zenith in the last London-Edinburgh.

**Joy Riding.**

People residing in famous touring districts, such as the Lake District, claim that almost as much pleasure riding is going on as ever before, but they should bear in mind that every holiday motorist on the road makes for such centres. Peace-time Bank Holidays found the Coventry-Kenilworth road alive with pleasure vehicles, but during the busiest hour of Bank Holiday this week we met but one motor cycle and one car while travelling between the two towns named, though the road was crowded with pedestrians and pedal cycles.

**Cancellation of Petrol Licences.**

In connection with the Order issued by the Petrol Control Committee cancelling petrol licences issued prior to April and May last, we append a letter sent by Major Stenson Cooke, Secretary of the Automobile Association and Motor Union, to the Secretary of the Board of Trade, under date July 31st:

**"Re PETROL LICENCES.**

"Sir,—With reference to the notice issued by the Petrol Controller whereby full duty petrol licences for private motor cars and motor cycles issued prior to April and May last are cancelled, I am directed to submit a strong protest on behalf of many thousands of members of the Automobile Association and Motor Union.

"Motorists holding such licences have always been given to understand that they were under no compulsion to draw their monthly allowances as they fell due. Moreover, this Association has been informed by the Petrol Control Committee that by refraining from exercising their licences, motorists would always reserve the right to obtain such allowances at a later date.

"I would add that many motorists, relying upon the assurance of the Petrol Control Committee that they were entitled to do so, have saved their small allowances for consumption during their annual vacations. . . . They have been encouraged to do so by the following answer given in the House of Commons on July 16th last by Mr. G. Roberts to Mr. Cathcart Wason:

"It is probable that there is still a certain amount of motoring for pleasure carried on by owners of cars who are using up stocks of petrol, in respect of which licences have been issued in the past. There is no penalty for such motoring, but licences for petrol are now issued only to persons who use their cars for public or business purposes.

"It is submitted that sudden cancellation of unexhausted petrol licences inflicts unmerited hardship upon those who have conscientiously supported the Government by economising in petrol, while others have regularly drawn their allowances for business or pleasure purposes.

"I am, sir, yours faithfully,

"STENSON COOKE, Major."

**Motor Cycles for American Army.**

Contracts for \$988,000 worth of motor cycles were awarded on July 19th by the War Department of the United States on bids submitted recently at the Quartermaster's Depot. The largest portion of the order went to the Hendee Manufacturing Co., which has accepted the contract to supply the Government with 2,500 twin Indian motor cycles. The remainder of the order went to the Harley-Davidson Motor Co., which is to supply the United States Army with 1,500 Harley-Davidsons. The motor cycles are to be bought at a uniform outside price of \$247 apiece, and the manufacturers have undertaken to make several more or less radical changes in the design to bring the machines more nearly into conformity with standard specifications threshed out at Washington on June 28th by members of the motor cycle trade and Army officials. The order also calls for a cancelling of private order work now going through the two factories until the Government's first really big order has been consummated.

**A Series of Harley-Davidson Triumphs.**

Before a crowd of fully 7,500 spectators, mostly enthusiastic motor cyclists, Otto Walker, on a Harley-Davidson, carried off a great victory in the 100 mile event for professionals on the Sheephead Bay Speedway on July 12th. Walker made fifty laps on the two-mile board track in 1h. 17m. 0<sup>3</sup>/<sub>4</sub>s., having led thirty competitors throughout the greater part of the race. Harry Smith, another Harley-Davidson rider, piloted a second machine of that make into second place. Mike Costello, yet another Harley-Davidson rider, together with Leslie Parkhurst, on the same make of machine, took third and fourth places. The fifth place was secured by George Hamilton, riding an Indian. Average speed, 77.9 m.p.h.

There were so many entries for the six-mile sidecar event that it had to be run off in heats. Thomas Monte won the first heat by a narrow margin from August Landan (both of whom were riding Harley-Davidsons), the time occupied by the winner being 6m. 19<sup>1</sup>/<sub>2</sub>s. The second heat was won by Jacob Henkel (Harley-Davidson) in 6m. 41<sup>3</sup>/<sub>4</sub>s., while another Harley-Davidson was second in the same heat. In the final, Henkel just succeeded in beating Landan on the line, the time taken being 6m. 12<sup>3</sup>/<sub>4</sub>s. As both Landan and the third man were riding Harley-Davidsons, all three places went to this well-known make. Average speed, 58 m.p.h.

Harley-Davidsons again proved victorious in a four-mile amateur race, coming in first, second, and third. The time taken was 3m. 13<sup>3</sup>/<sub>4</sub>s. Average speed, 74.4 m.p.h.

The twenty-mile amateur race for stock machines was won by Joseph Farrell on an Indian; time, 15m. 37<sup>1</sup>/<sub>2</sub>s. In this race Harley-Davidsons took both second and third places. Average speed 76.9 m.p.h.

A feature of the meeting was an exhibition ride, on an eight-valve Indian, by Arthur Chapple, in full uniform. He covered a distance of two miles in 1m. 25<sup>1</sup>/<sub>2</sub>s., and received a great ovation from the crowd of spectators. Average speed 84.5 m.p.h.

**Critical Petrol Position.**

Middlesbrough tradesmen have pointed out that more horses could be released and an economy in cereals effected if more petrol were distributed for business purposes. The Town Clerk has received a reply from the Petrol Control Department, stating that the petrol position is extremely critical, and that unless there is some material improvement in the situation Sir Evan Jones is not prepared to release any further supplies for civil and industrial needs.

**AVERAGE PRICES.**

WE give below the prices of second-hand machines offered for sale in the last issue of *The Motor Cycle*, and in the adjoining column the average prices based upon the latest figures available. Thus the general trend of the market is visible at a glance, though in the first column many blanks inevitably occur. This is due to an insufficient number of one model on which to base an average. The word "combination" indicates a sidecar outfit as supplied by the makers, while "sidecar" implies that the fitting has been carried out by the owner.

## Second Instalment: FORCE.

The first instalment appeared on July 19th, 1917.

It is hardly necessary to point out to thinking motor cyclists the great desirability of a little mathematical knowledge—so many questions may crop up, as, for instance, the horse power required to mount a certain hill, the tension of a belt or chain when driving a heavy machine, or the calculation of a gear, that the man who is entirely ignorant of these matters must often be at a loss. In this and the following articles (of which there will be several) the author proposes to discuss some of the simpler problems dealing with speed, acceleration, force, inertia, centrifugal force, etc., and their practical application to everyday questions in a popular manner without unnecessary technicalities. No motor cyclist, therefore, need pass by these articles under the impression that they are beyond his understanding, for everything is explained in simple language.

**M**OTOR cyclists as a class have exceptional opportunities of verifying the definition that "Force is that which causes motion." At any rate, they are well aware that motion cannot be produced without the application of force, though they have doubtless learned by bitter experience that there are occasions when a prodigious expenditure of force causes no motion whatever. To meet such cases as the latter, the definition must be expanded into the following form: "Force is that which changes or tends to change a body's state of rest or of uniform motion in a straight line." The emphasis in this statement should be laid on the word "changes."

The mere fact that an object is in motion gives no indication as to what (if any) forces are acting on it; if the motion is uniform, the explanation may be either that no force is being applied or that a number of forces are in operation whose effects neutralise each other. For instance, a motor cycle romps up a stiff gradient at a steady 30 m.p.h. not because no forces act on it, but because the propulsive force exerted by the engine exactly balances the effects of gravity, of wind resistance, and of road friction. Similarly, absence of motion by no means necessarily implies absence of force—a ship may remain motionless on the water either for the reason that no (horizontal) forces are in operation, or because the considerable forces exerted by wind and tide are balanced by the pull of the anchor chain. But if the body *changes* its speed—if it undergoes acceleration or retardation—then it can be said with absolute certainty that one or more forces must be at work on it.

### The Cause of Engine Vibration.

The connection between the force acting on a body, the weight of the body, and the acceleration produced,

is one of the most important in the whole of mechanics. It is, however, extremely simple:

Force (lb.)

$$= \frac{\text{Weight (lb.)} \times \text{Acceleration (feet per sec. per sec.)}}{32}$$

The application of this law to some of the motions of a motor cycle engine yields rather interesting results. Taking as an example the motion of the piston, this component and its attachments are subjected to rapid and violent accelerations, for during the first half of each stroke the piston rapidly increases its velocity from zero to quite a high figure, while during the latter

part of the stroke a correspondingly rapid retardation must occur. In a  $3\frac{1}{2}$  h.p. engine turning at 2,000 r.p.m., the maximum value of the acceleration will probably be of the order of 7,000ft. per sec. per sec. If the weight of the piston is, say, half a pound, we find that the force required to accelerate it will be  $\frac{1}{2} \times 7,000$  lb., which is

$\frac{32}{2} \times 7,000$  roughly 110 lb. It is this force that is responsible for the more or less objectionable engine vibration with which all riders are familiar.

It may also be profitable to examine the motion of the valves, which are evidently subjected to very considerable variations of velocity. With a valve lift of 0.4in., and engine speed of 2,000 r.p.m., the acceleration of the valves, tappets, etc., will attain a value, in round numbers, of 2,000ft. per sec. per sec. Taking the weight of one valve together with all the parts that move with it at 0.2 lb., the force necessary to produce the requisite rapidity of opening and closing is

$$\frac{0.2 \times 2,000}{32} = 12.5 \text{ lb.}$$

This figure at once explains the necessity of the powerful springs that are called for in controlling the valves of high speed engines.

Action and reaction are equal and opposite. Notice that the tension of the spring is the same, whether the spring be fixed to a post or held by a second man pulling in the opposite direction.

**Mechanics for the Motor Cyclist.—**

There is one fundamental law of mechanics that many people find great difficulty in understanding—"action and reaction are equal and opposite." Translated into everyday language, this statement means that if you push a wall with a force of 20 lb., the wall will push back at you with a force also of 20 lb. The force exerted by you is the "action"; the equal and opposite force with which the wall retaliates is the "reaction." The doubtful point is, *does* the wall put forward this alleged reaction? How can a rigid, inanimate body exert a force? The accompanying sketches may be helpful in settling this question. *A* in the first diagram is represented in the act of trying his strength by means of a rope attached to a post, a spring balance indicating what pull he exerts. Suppose the force registered on the balance is 150 lb. If we now substitute for the post another human being *B*, we know perfectly well that *A* can only maintain his pull of 150 lb. as long as *B* also pulls in the opposite direction with a force of 150 lb.; that is, *A* is prevented from toppling backwards only by the effort that *B* exerts. But since, when pulling against the post, *A* felt in no danger of being let down,

clearly *something* must have been holding him up with a force of 150 lb. The only agency that can exert this force is the post; in other words, the post is pulling against *A* just as definitely as *B* is. If *A* is impervious even to this reasoning, let us try a more drastic proof. Let us impress upon him that while moderate strength rings the bell, great strength returns the penny, and then we will surreptitiously cut the rope at *c*. If the ensuing shock does not carry conviction to his mind, nothing will!

**Action and Reaction propels the Motor Cycle.**

The reason why I have to some extent laboured this question of action and reaction is simply this, that if action and reaction were not equal and opposite, I should not be writing these articles at all, for there would be no motor cyclists to read them. For what is it ultimately that propels a motor cycle along the road? Nothing more than the reaction of the road surface on the back tyre. The engine causes the tyre to exert a *backward* force on the road surface; the road exerts an equal and opposite reaction on the tyre, and this it is that pushes the machine forward.

MOHANDIS.

*(To be continued.)*

## That Hot Spot.

RECENT comments on the subject of a hot spot in the piston call to the writer's mind his experience with a machine he possessed in pre-war days. The machine was a P. and M. of unusual kick and vitality—a picked machine.

The mount possessed one unaccountable peculiarity, in that the crank case always became so hot that one could hardly bear to touch it. It was a marvellous machine, wonderfully efficient in every way; the cylinder and piston were a dead true fit, rings beautifully faced all the way round, and so on, and that the heat of the crank case was not due to conductivity I proved to my own satisfaction by

placing a fairly thick asbestos washer between the cylinder and crank case. The only trouble the heating caused was that the inside of the piston made up with carbon in a surprisingly short space of time. Why? The compression was varied to suit the various conditions of riding, but the mystery was never solved. Can any reader explain?

Possibly the piston warped slightly when heated up, but it is rather strange that the engine ran very much better when thoroughly hot.

CHINOOK.

WHERE THE B.L.I.C. MAGNETO IS MADE.

Fireside Chats on  
Motor Cycle Problems

## CHAIN OR BELT DRIVE?

"I WAS testing a topping little machine to-day," announced the Journalist. "A T.T. flat twin, which very nearly flew. But the day being wet, I was let down horribly by the belt drive." "What do you mean by that?" snorted the Manufacturer, who rather favoured belt drives.

"Just this. The day being wet and the roads being wet, the belt gave trouble, as belts invariably do under such conditions. The man with me was riding an all-chain Norton. On the outward journey I could leave him standing, except on the hills, but after thirty miles of it the fun began. On the return journey he beat me every way—simply because I could not accelerate without belt slip. I felt like a winged duck with a spaniel after it, and at the end of the run he had beaten me hollow on petrol and oil consumption—simply on account of my beastly belt drive."

"I have had the same experience," announced the D.R. "In my opinion, the modern chain-cum-belt drive is no better as regards the nuisance of slip than was the direct belt drive of yesterday. In the latter you lost on the small pulley, but you gained on the length of drive—to-day you gain on the large pulley but you lose on the absurd shortness of the drive. Probably, therefore, the chief reason why the chain-cum-belt drive of to-day is considered superior to the direct drive is because we have better engines and good clutches, together with gear boxes, which combination enables one to maintain a more or less even torque on the belt. It goes without saying that belts, too, are infinitely superior to what they were."

### The Advantages of Both Systems.

"Look here, you chaps," broke in the Journalist, "I didn't mean to start a dispute. This matter has already been pretty well threshed out in *The Motor Cycle*. 'Ixion' has put the case clearly and with his usual remarkable conciseness. A fortnight later 'Chinook,' inferring that he disagreed with 'Ixion,' said practically what 'Ixion' said, only in a different way. Let's drop it."

"No fear," returned the D.R. "The object of recording these disputes is, I presume, to present every side of the question from the points of view of different riders—to throw the subject on the threshing floor, as it were, and let everyone have a bat of it. To debar a subject just because a few old hacks have earned their weekly salaries out of it is not fair. Go ahead, Novice. Let us hear what you have to say."

So the Novice, who had been restive for some moments, spouted out that he couldn't understand why so many had their knives into the belt drive. "If a man is addicted to riding an all-chain machine, he curses the belt drive black and blue, and *vice versa*. I think motor cyclists are the most narrow lot of blighters I have ever run up against. The fact is that what you lose on the swings you gain on the roundabouts. Each system has its recommending features—each its defects. I have owned both, so I know."

### Belts Save Tyres.

"Quite right," agreed the D.R., "only you are wrong in one respect. It is not the man who owns a chain drive that curses the belt. It is the man who owns the belt drive that curses it. Go ahead."

"Well, then, take my own experience. My last sidecar twin—6 h.p.—was fitted with belt drive; and though in wet weather I sometimes cursed the belt, it saved me pounds during the three years I had the machine. Do you know that my rear tyres lasted 6,000 miles?—whereas 3,000 is jolly good for a chain-driven twin. The petrol consumption of that machine was marvellous—in fact, it was cheaper to run than the 2½ h.p. two-stroke solo that I owned at the same time."

The Journalist grunted, the D.R. snorted disdainfully. "You are going back to a bygone era in advocating the belt drive for sidecar twins," said the D.R. "It is an admitted fact that the belt drive in any shape or form is off the map for anything but solo mounts. The only point to be argued is as to whether it is suitable for the solo mount."

"I agree," said the Novice, who was quite a sport. "I have merely held up my experience to prove that the belt drive is infinitely cheaper."

"It amounts to this," said the Journalist—"the belt drive is superior to the chain drive simply in the respect that it is, in itself, a shock absorber. A shock absorber arranged as part of the transmission system cannot be made to function to the best effect under all conditions. It must be hand-controlled. In a belt drive we have elasticity as well as slip, but if the average rider could be depended upon to use his clutch as a shock absorber as well as a clutch, there is no reason why he should not obtain results from his back tyre as good as with a belt. With a chain drive at low speeds one must finger one's throttle lever and one's clutch *not* individually, but together; therefore the chain drive demands better driving."

"The Americans realise this," stated the D.R., "and therefore they give you a clutch arranged to act as a shock absorber. The only reason why British riders obtain such poor results from their back tyres with all-chain drive is because they are afraid of using their clutches. A clutch is there to be used; insets wear indefinitely, and even when worn out they are cheaper to renew than tyres and engine bearings."

### The Keynote is Simplicity.

Here the Manufacturer, who had for the most part maintained silence hitherto, had something to say. He said that absolute simplicity was surely what we are aiming at. "Well, look here," said he. "Just think what complications you introduce with the all-chain drive. You admit that you must have an efficient clutch and an efficient shock absorber. The latter is the most awful compromise that modern engineering ever ran foul of. No two engineers can agree where it should be placed, or what form it should take. You yourselves admit that unless it be supplemented by judicious fingering of the clutch it is practically useless. Then take chain cases. These are beastly things to handle; the chains themselves are unclean, while the cases are costly to make, difficult for the amateur to handle, and, moreover, they add a dozen difficulties as regards accessibility. The belt-driven machine is the simpler, the cheaper, and the more efficient. Why, then, do you condemn the belt drive? Simply because it is susceptible to the weather. So is the chain drive, though it does not let you down. I tell you this, that the weaknesses of the belt drive lie not in the system itself, but in its application."

"Then why the deuce don't you manufacturers buck up and give us a belt drive which is applied in the right way?" queried the D.R. "You admit that you like it, and that its weaknesses are at your own doorstep."

The Manufacturer admitted that the design of many belt drives was appalling. "Sometimes the mudguards appear to be arranged purposely to direct water on to the belt, while no provision whatever is made for sheltering the drive from water and oil. I consider," he said, "that the chain-cum-belt drive is ideal for a solo mount, and it is quite possible to eliminate most of its present defects. Unless some effort is made in this direction it will most assuredly be superseded, so makers who favour the belt drive had better get to work on revising their mudguarding, etc."

## A 4 $\frac{1}{4}$ h.p. B.S.A. ON THE ROAD.

### A SUCCESSFUL 1,000 MILES WITH A 1917 SIDECAR.

**T**HE B.S.A. motor cycle has a name for reliability—a matter of primary importance in view of the restriction on repair work—and my experience has fully maintained this reputation.

My mount is a 1917 Model K, chain-cum-belt drive, with semi-T.T. bars, and is coupled to a fully-equipped Montgomery sidecar, finished in cream and green to match the B.S.A. tank. The tyres are 2 $\frac{1}{2}$  in. Palmer Cord on all three wheels, to allow for interchangeability, which ensures equal wear and eliminates a lot of anxiety on long journeys. A machine possessing wheels which can be easily removed without disturbing brakes, and interchangeable tyres, constitutes the next best thing to interchangeable wheels, at a fraction of the cost. The magneto is a C.A.V. which deserves to be more universally adopted. It is absolutely reliable, and possesses a number of good points which are a distinct change from the stereotyped Bosch design. The other fittings include a Stewart speedometer mounted on a home-made bracket carried by the mudguard stay fixing screw to allow of the front wheel being removed without disturbing the drive, and a complete set of electric lamps. These are fed from a C.A.V. 6 volt 24 amp.-hour battery, carried under the sidecar seat and controlled by an ordinary trembler switch near the passenger's right hand. The wiring is carried out with brass-armoured twin cable, as used on cars, and detachable plugs are fitted at all the lamps and at the point where the cable enters the sidecar to permit of the removal of any lamp or the complete sidecar without upsetting the permanency of the installation. The set has proved perfectly reliable, and is quite immune to weather conditions.

A well-equipped outfit. The Montgomery sidecar is finished in cream and green. The electric lamps are fed from a C.A.V. 6 volt 24 amp. hour battery carried under the sidecar seat.

The owner, Mr. Francis E. Schofield, aboard the 4 $\frac{1}{4}$  h.p. B.S.A., of which he speaks highly.

Since January the outfit has seen some hard service on our lorry-wracked roads, and in spite of infrequent attention has never once let me down. In the 1,000 miles covered the only breakage has been a top recoil spring on the front fork, which the B.S.A. people kindly replaced. The spring fractured through meeting unexpectedly a succession of pot-holes on the Birkenhead-Chester road, when travelling at close on 30 m.p.h.—an experience which would have spelt disaster to a less sturdy machine. By reducing the speed below 20 m.p.h. I was able to reel off a further forty-five miles the same day before removing the broken spring.

#### Tyres and Transmission.

My luck has been "in" with regard to tyres; none of the three has punctured, and only the back cover shows signs of wear. The parallel ribs on the tread are not more than half worn down, which indicates that the tyre is good for at least another 1,500 miles, with a probable extension by transferring to another wheel. The belt, a 1 in. Dunlop, is in perfect condition, thanks to the sensible size of the countershaft pulley, and has never been touched. On two occasions the eccentric back wheel spindle was revolved slightly to take up the stretch, and this represents the sum total of the attention devoted to the transmission. The front chain has given no trouble, and would still be awaiting its first inspection but for the fact that a reduction in gear ratio necessitated opening up the chain case to remove the existing engine sprocket.

For the engine I have nothing but praise. It will pull for miles on end with an entire absence of effort, and has improved considerably in tune

**A 4½ h.p. B.S.A. on the Road.—**

after a carefully nursed running-in period of about 150 miles.

**Carburettor Adjustment.**

The B.S.A. carburettor is an ideal device for the experimentalist, and allows of an infinite variety of jet openings by turning the milled screw. By careful investigation I arrived at the most economical jet opening, which corresponds to a one-half turn of the screw from closed, and I provided a hot air extension pipe from the air intake to the engine cylinder ribs to ensure that perfect vaporisation took place. As a result the running is almost noiseless on the flat at 15-18 m.p.h., and ample acceleration is obtained, in spite of the fact that my total average consumption is almost 72 m.p.g., and has reached 76 m.p.g. on individual journeys. Incidentally, I might mention a considerable reduction in valve clatter can be made by reducing the tappet clearance to paper thickness only.

Traffic driving was materially simplified by adjusting the throttle and air barrels to allow the engine just to tick over in free with the levers shut off. It is delightfully convenient placidly to take one's place in a string of waiting vehicles, ready for the first sign of motion ahead, with the engine revolving almost inaudibly beneath, without having recourse to frantic grabs at the exhaust lever to restrain the youthful exuberance of a well-tuned big single.

For lubricating the engine I use B.S.A. cylinder oil impregnated with Oildag, and can vouch for the satisfactory nature of the latter product.

**Speed and Power.**

With regard to the machine's capabilities, I have found the engine, in conjunction with the three-speed gear box, quite equal to tackling all ordinary main road hills even with a fully-loaded sidecar and week-end luggage. I should have no fear of undertaking an extended tour, if circumstances only permitted, confident of climbing everything encountered.

As regards speed, I seldom attempt anything spectacular, preferring the humble 20 m.p.h. average and ability to climb main road hills, as mentioned, as sufficient for my personal requirements, but a few days' vacation in N. Wales suggested experiences of a sporting nature, and, time being of no account, a few attempts were made on some local "pimples." These chiefly consisted of disused cart tracks, which lent little opportunity for speed, but provided good fun at impromptu hill-climbing, with the exception of a fairly level stretch of about one mile in moderately good condition. With a male occupant of the sidecar weighing 11 stone, the speedometer needle rapidly rose to 46 m.p.h. on this level stretch, and this speed was maintained for the full distance. A second attempt the following day under more favourable conditions with a slight following breeze, but carrying an extra male passenger on the carrier, yielded even better results. With a total load of 32 stone, the engine accelerated until the needle reached the 45 mark, and maintained the speedometer reading dead steady to the end.

**Summary.**

Summarised, my results are as follow:

Total miles covered, 1,000.

Total petrol consumed, 14 gallons.

Cost of petrol at 2s. 8d., £1 17s. 4d.

Average miles per gallon, 71.4.

Cost per mile for petrol (average), 0.448d.

Total oil consumption, ¾ gallon.

Miles per gallon (oil), 1,330.

Maximum speed on top gear with passenger, 46 m.p.h.

Minimum speed on top gear with passenger, 10 m.p.h.

Minimum speed on bottom gear with passenger, 3 m.p.h.

The total cost per mile cannot be given, of course, owing to the impossibility of bringing depreciation into the reckoning.

FRANCIS E. SCHOFIELD.

**BREAKING THE TEDIUM OF CONVALESCENCE.**

The blue cover of *The Motor Cycle* is familiar in most of the hospitals for wounded soldiers, the convalescent in the foreground evidently preferring it to cards. The hospital is at Abbots Ripton, near Huntingdon, the home of Lady Guernsey, who is seen in the background.

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

#### SOME FUEL.

Sir,—While waiting at a garage a curious incident happened. A man on a machine, which looked like a Zenith, rushed into the garage for petrol. The garage man told him he could not have it, so he demanded water, and shouted to the stupefied mechanic to hurry. When the water came, he seized the can and quickly poured its contents into the tank, which soon overflowed. Then he rushed away up a long hill, leaving all present in a state of great amazement.

Did he stop the other side of the hill? Can any reader of *The Motor Cycle* explain this?

R.E.C.

Camberley.

#### A LUDICROUS DERANGEMENT.

Sir,—Referring to a paragraph in your issue of April 19th, commenting on a complaint made by a B.S.A. rider that his machine went better uphill than on the level, it might interest you to hear that I had a similar experience with my B.S.A. (all-chain drive) a few months ago.

I attribute the derangement to weak valve springs. I only experienced the trouble while I was using a pair of springs purchased locally, and obviously weaker than those provided with the machine. These very soon broke, and were replaced by stronger springs. The trouble at once vanished, and has not reappeared.

H.R.J.

Kuala Lumpur, F.M.S.

#### PETROL FILTERS AND DIVIDED TANKS.

Sir,—Your correspondent B. C. Woodward, who wrote with reference to petrol filters and divided tanks, is apparently unaware of the fact that the majority of active service aeroplanes are fitted up with pressure-fed petrol systems, so that partitions, as he suggests, would be useless, unless each were fitted up with a separate pressure system, which would entail considerable complication for a tank of several compartments.

All tanks in use, however, with few exceptions, have several internal partitions, but these are for strengthening purposes solely.

Moreover, I doubt if there is a single machine in use on active service without a filter somewhere in the petrol system.

C. K. SHEPHERD (Lt. R.F.C.).

#### POLICE INTERFERENCE.

Sir,—Being a regular reader of *The Motor Cycle*, and having read of the stopping of motor cyclists, I herewith append questions asked of myself and friend on a recent Sunday in a St. Helens main thoroughfare by the police.

Name and address, age, where employed, occupation; whether riding on business or pleasure; if using petrol (show petrol licence), particulars of where petrol was procured; where had we come from, where going, and how long had we been away; if owner of machine (produce driving licence).

I was driving a combination with my wife and child and father-in-law, and when I told the police I was out for the benefit of the health of the last-named, who had had to give up work on account of illness, his name and address were asked, how long he was staying, when he came, and when he would return.

After all this I was told I should be reported for joy riding, it being illegal. By this time there was a great crowd gathered, which we sorely resented.

The above occurred between 6.30 and 7.0 p.m.

H. ALDRED.

#### ALUMINIUM COOLING.

Sir,—In *The Motor Cycle* of July 5th and 12th reference is made to the use of heat ribs on cylinder walls in order to accelerate heat transmission, and a sketch is shown on page 12 of a cylinder provided with an outside jacket having ribs.

To my mind the arrangement would not produce much of the desired effect, owing to the want of molecular continuity of the barrel and the jacket. This could easily be proved by actual test made with water, as I did many years ago. Anyone interested in the application of heat ribs to cylinders for increasing the rate of transmission may care to look up one of my earlier patents of about forty years ago. Others may have done this before me.

D. H. HALPIN.

#### MOTOR CYCLISTS IN THE ARMY.

Sir,—In the "Blue 'Un" of July 12th I notice that your attention is called to the matter of D.R.'s receiving a reduced salary.

In this paragraph you make use of the following words: "This is almost as bad as the comparatively safe job of driving a car in the Transport Section."

Well, Mr. Editor, do you know what you really imply by the word "safe"? Would you care to come with us some night to the music of Fritz's shrapnel overhead?

I do wish people would really think about what they say before they put it in black and white; in other words, look at the M.T.'s casualty list, and oblige.

Fritz does not care about D.R.'s, it is we chaps he is after.

FRANK TURNER DENTON.

[Our correspondent has quoted us incorrectly. Driving a car in the Transport Section was referred to as comparatively safe, not with reference to D.R.'s, but compared with service in the trenches. Surely no one can deny this! We have certainly no wish to belittle the excellent work done by the A.S.C.—Ed.]

#### PILLION RIDING.

Sir,—With reference to your recent paragraph concerning that most enjoyable and economical form of motoring, pillion riding, perhaps you will allow me to offer a few useful hints conducive to safety. Some years' experience of passenger carrying pillionwise have convinced me that the best kind of mount for this purpose should be fairly heavy with a very strong frame, low built, equipped with multi-cylinder engine, handle-bar clutch control, all-enclosed chain drive, strong wheels with 3in. tyres, and security bolts. The pillion seat should be upholstered and sprung at each corner, with guides to prevent side play, similar to the Tynesider. A three or four-speed gear box is a *sine qua non*, particularly when riding in a hilly district on narrow roads, where one is likely to be baulked when climbing.

The passenger should sit as close as possible to the driver, but as there is more play in the saddle than obtains with the pillion seat a margin of one or two inches between the driver and passenger should be allowed for, so as to prevent undue wear and tear when pot-holes are encountered.

On no account should the passenger be much heavier than the driver: the lighter she is the easier will be the steering.

The driver should wear a strong leather belt, and insist upon the passenger holding it. The passenger should deprecate any kind of swank on the part of the driver, such as indulging in unnecessary bursts of "high" speed,

accompanied by much wobble, sound, and dust. These "all out" stunts frequently finish up "all in" before the "beak" for loitering or what not. Better by far try to convince Lottie that your "grid" is some 'bus and that you are some driver by frying the breakfast bacon on your cylinder head when you arrive home in time with the milkman. It is surprising what an early Rex will do if humoured a bit! Other forms of swank consist of the passenger disdaining to hold the belt of the driver, with the result that a bad pot-hole unexpectedly encountered unseats her and the law of gravity sees to the rest. Then there is the "knot" with the extra wide handle-bars on a baby two-stroke steering with one hand only whilst he deftly flicks the ash from his woodbine with the little finger of the other hand. Also has the reader noticed the effect of certain freakish drain pipe exhausts on the passenger's light summer-go-to-meeting dresses, etc.? The *basso profundo* growl of the angry exhaust may possibly imbue her with a certain respect for the enormous amount of reserve power it suggests, but all respect at once vanishes immediately she discovers the appalling truth that her trousseau has been hopelessly ruined by "that horrid smelling thing." Moreover, she may probably wish to borrow a pint of "juice" for cleaning purposes.

VIC.

Golder's Green.

### CHANGE TO MORE POWER.

Sir,—I have read *The Motor Cycle* ever since I started motor cycling five years ago, and have marked, since the war, the number of your readers who have left their first mounts for something else, usually on a bigger scale. I began with a 6 h.p. sidecar machine, and have been driving a motor 'bus now for over two years.

ANNIE BALCHIN (Mrs.).

### BALL BEARING CONNECTING RODS.

Sir,—In following the animated discussion of the above, it appears to me that not a few of your correspondents fail to embrace as a whole all the forces operating on the piston. In your issue of the 19th ult., Frederic Strickland compares the motion of the pistons in a rotary engine to that of a ball being whirled in a circle at the end of a piece of string, and asserts that in his experience the string always remains taut. May I ask him a question? If the ball at every other revolution received a blow in a direct line with the string (representing the explosion in the cylinder), would the string always be taut?

In his example the string remains in tension, yet a moment's consideration will reveal to him the fact that the connecting rods in a rotary engine are under compression during three of the four operations in the cycle, viz., compression, explosion, and exhaust, and are in tension during the suction stroke. It is this change from compression to tension that gives the reciprocating effect to the bearings. I say "effect," being fully aware that the pistons do "actually" reciprocate along the cylinders.

PERCY J. FOSTER.

### AVERAGE SPEED.

Sir,—As an appreciative reader of your splendid paper for twelve years, I am tempted to write to you on a subject which has always been much debated by motor cycling friends and myself. I refer to the average speed of various types of motor cycle, so interestingly discussed in your issue of July 19th by "The Critics," whose articles are, after Occasional Comments, most eagerly read by me when I get your paper, which is sent out to me every week.

In civil life I suppose I cover about as many miles weekly as anybody, as business alone takes me something like 750 miles per week on an average, and on several occasions I have finished up the week with a distance of 1,000 miles to my credit, or, should I say, to the credit of the various machines I have owned.

I had a 1911 two-speed  $3\frac{1}{2}$  h.p. Humber, which carried me 59,000 miles, and though this was rather slow, being very heavy, I have frequently travelled from Hungerford to Reading, twenty-six miles, in forty minutes.

But the best machine I ever owned, alike from the point of view of reliability, cheapness of running, comfort, and high average speed, was my old 1914 4.5 h.p. model C Zenith. On this machine, which I sold with 31,000 miles to its credit, I once did 284 miles in eight hours fifty minutes, including all stops, three for petrol and one for a meal. Of course, I did this from necessity, it being

imperative that I should return to Reading in time to catch a friend who was leaving that town. I might mention that from York to Hatfield I was on the Great North Road, but prefer to suppress any further details for various reasons. On this run I raced and beat a very hot 15.9 h.p. Straker-Squire in a scrap which lasted twenty-two miles. I might also mention that I got very badly left by the rider of a T.T. Scott on a hilly portion of my route, for, though I could give him more than he wanted on the flat, up hills with sharp corners he was easily "all over me."

Speaking of shorter distances, a certain nine miles of beautiful Tarmac (for it was *avant la guerre*), very well known to Reading motor cyclists, I used regularly to cover in eleven minutes, but then this road is practically dead straight and flat, and there are no villages or other obstacles to speed.

On the whole, I think your "Critics" are not far wrong in the conclusions at which they arrive, for I used to reckon that my average for the whole of my daily wanderings, reckoning, of course, only actual travelling time, worked out at about thirty-one miles per hour. I used to keep an accurate daily chart of my mileage, and I could usually estimate time spent during stops pretty accurately, because, though I did not pay my calls by appointment, I had certain times when I knew I could certainly find my clients at home.

There has been much argument here amongst our motor cyclists regarding the speed of which their Triumphs and Douglasses were capable. I will not mention how the matter was finally settled, for fear the "powers that be" might enquire anxiously if we have nothing better to do, but I will say this: the motor cyclists were very disappointed. Which goes to prove that the "D.R." was quite right in saying, "The average rider has an enormously exaggerated notion as to the maximum speed on the level that his machine will attain."

In case anyone should think from my unstinted praise of the Zenith that I have an axe to grind I would like to conclude by saying that I have no financial interest whatever in the firm.

If one of the other motoring papers which are sent out to me fail to arrive I try to take it as philosophically as possible, but if *The Motor Cycle* is missing, oh! what a moan!

I trust I have not encroached too greatly on your valuable space, and hope for a speedy return of the good old days on the open road with something that can shift between one's knees.

ELDON.

B.E.F.

### SIDECAR AND REAR LIGHTS.

Sir,—We read with pleasure and interest "Glow Worm's" letter appearing in your issue of July 26th. He is good enough to refer to the Voltalite as a wonderful little machine.

There is one warning, however, we would like to give your readers who may be induced, on "Glow Worm's" recommendation, to make use of the pedal cycle Voltalite on a motor cycle, and that is, that the pedal cycle Voltalite, though thoroughly strong and reliable for the ordinary push bicycle, is not, according to our standards, sufficiently substantial for a motor cycle; and though it is a tribute to the Voltalite that it is working so well on a number of motor cycles and sidecar attachments, we do not think it desirable, in view of the vibration and high speed of the motor cycle, to fit the pedal cycle Voltalite.

We manufacture a special Voltalite fitted with Hoffmann ball bearings for motor cycle use, and it would be better if this were used.

We do not think we are giving any secret away when we inform your readers that we have ready for prompt supply after the war an improved model of motor cycle Voltalite, which will illuminate head lamp, side lamp, and tail lamp. It has none of the complications of the accumulator charging generator, but it will permit of the light being turned on when the motor cycle engine is not running.

As "Glow Worm" states, he does not know us, we do not know him, but we would like to express our thanks to him for his kind appreciation of the Voltalite, which we can assure him is absolutely British in manufacture and design.

WARD AND GOLDSTONE.

Many interesting letters are unavoidably held over owing to lack of space.

# QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of the envelope, and should be kept distinct from questions bearing on technical subjects.

## Storing Tyres.

Having got a new B.S.A., and being unable to obtain petrol, I should be pleased to know which is the best way to keep the tyres in good order while being stored.—S.R.

The best way to keep the tyres in order is to remove them from the machine and to hang them in the dark in a damp place. Inner tubes may be placed in a box with French chalk.

## Lubrication.

I have an Enots oil pump fitted to my machine, and have noticed my oil will not turn off. Even when the valve is closed down on to its seating the oil continues to drip, but only when the machine is running. On taking the pump out of the tank, I noticed that the wire gauze, which is fitted in the bottom of the pump, is missing. Is this the cause of the trouble?—R.E.T.  
No; the absence of a wire gauze is not the cause of the trouble, which is probably due to the needle valve not being a good fit, being in need of grinding in. This can be done with very fine emery powder and thin oil.

## Lighting Regulations.

(1.) Am I obliged to have two head lights, one on the motor cycle and the other on the sidecar? (2.) What is meant by a reduced light on an acetylene head light? (3.) What is the size of glass one is permitted to have? What is the farthest distance the light must reach? (4.) If the light is turned or reduced low, is this sufficient with the glass partly, not fully, obscured? I have been held up by the police for the above. I previously made enquiries, but was told I did not need a lamp on the sidecar, and if the head light was reduced I was in order.—J.W.G.

(1.) Yes, you have to carry a lamp on the sidecar as well as a head light on the motor bicycle, to show the width of the vehicle. (2.) Painting the glass with a coat of white paint or pasting a sheet of tissue paper on the outside. (3.) The glass must not exceed six inches in diameter. The farthest distance the light must reach is not stated outside the Metropolitan area. (4.) The whole glass of a motor cycle head light must be obscured in the manner mentioned above. By turning the light low you would probably experience a smoky flame and burner trouble.

## Carburettor Adjustment on Two-stroke.

As an old-time cyclist well past middle life who has recently taken to motor cycling, I should like to have your kind assistance.

On a reliable two-stroke fitted with a Senspray carburettor I find that the engine will not fire evenly unless the gas lever is advanced to about level with the air lever when fully open. These positions give a speed much too fast for my liking. The size of the jet is 28.—J.W.R.

We doubt if you will be able to remedy the trouble of which you complain, because a two-stroke engine is not so flexible as a four-stroke, and it is often difficult to throttle down with it. You might try the effect of a larger jet, which would give a stronger mixture at slow speeds, but would probably increase the petrol consumption.

## IMPORTANT NOTICE.

### GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD

## An Electric Cycle.

(1.) Is it possible to use an electric motor with accumulator as motive power on a push cycle, and if so, what voltage, etc., would be necessary for such a motor? (2.) Would it be possible to generate sufficient power by a dynamo while pedalling to refill the accumulators for the motor? (3.) What would be the approximate mileage obtainable on one charge, and what m.p.h.?—E.M.S.

(1.) It is possible to use an electric motor for the purpose of propelling a pedal cycle, but the great weight of the accumulator renders the idea impracticable. (2.) This would be quite impossible, and if it were possible it would entail a great waste of energy. (3.) We doubt if you could get much more than ten miles on a charge, while the speed would depend upon the size of the motor fitted. It is really not worth going into figures as to the voltage and size of the motor, as the idea cannot be put into practice.

As early as 1901 a racing tandem was fitted in this manner, and was only suitable for use on the track or for very short sprints.

## Two-stroke Lubrication.

I have a Royal Ruby two-stroke 2½ h.p. It has run well up to the last week or two, and the engine did not get hot until I had run twenty or thirty miles.

Now it gets hot if I run one and a half miles and stops, and will not pull me until I have let the engine cool about four minutes. I have cleaned the carburettor and removed the carbon from the cylinder; also seen that there is no air getting to the petrol. This machine is oiled from the petrol tank, and I would like to know how much lubricant I should mix with the petrol. I have been putting one gill to every gallon of petrol.—L.E.

It is practically certain that your trouble is due to an insufficient quantity of lubricating oil. The correct proportion should be half a pint of oil to one gallon of petrol. If the trouble is not cured, after increasing the supply to the quantity stated above, we should recommend you to make sure that the vent in the tank filler cap is not stopped up.

## Chain Lubrication.

I should be very glad if you could tell me of any preparation that I could put on the chains of my motor cycle. I use sticks of graphite and grease mixed.

This is all very well for about six miles, but the stuff soon flies off. It is quite suitable on a cycle chain which revolves comparatively slowly, but on a motor cycle chain the speed of the revolutions throws all the stuff off in a very few miles. It seems to me that these chains require a more sticky and tenacious grease. I shall be glad to have your advice, as the chains run so much more smoothly when they have grease on them. My trouble is that it will not last on them long enough. As the chains have stretched I cannot now use the chain cover, and there is no room to shorten them by removing half a link, so they are exposed.—H.N.

Wash the chain in paraffin, and leave it to soak all night, and then plunge it into a bath of Russian tallow, which has been melted on the fire. This works the grease into all the links and bearings, and lasts for some time. When chains are entirely exposed they should be kept dry—that is, lubricated with a stiff grease rather than with a wet oil.

### An Accident.

**?** Recently I was in a collision between a car and my motor cycle in the following circumstances: I was proceeding along the Great North Road, going north. Just as I approached a by-road a car appeared, entering on the left, coming off the by-road on to the main road, along which I was travelling. I swerved to the right to allow the car to come on to the main road and pass me on its way south. But the car crossed straight over the road and collided with me on the grass. The insurance firm with which the car is insured claim from me for damage to the car, alleging negligence. Must I pay them? Can I legally claim damages from the driver of the car, or from anyone? (The driver was not the owner.) Had the car turned in, I have every reason to believe I could have got round it, but could not have cleared it by going straight on.—E.J.G.

Judging from your account of the accident, we do not think you can be held liable for the damage to the car, unless you were going too fast. On the other hand, we think you would be unlikely to succeed in any claim for damages from the owner of the car. The affair seems to have been a pure accident.

### Carrying a Gun.

**?** Would any of the readers of *The Motor Cycle* instruct me how to make a place suitable for carrying a gun in its case on the carrier of a motor cycle—I suppose that there is no room for so bulky an article elsewhere but on the carrier? I should want some kind of wooden bracket arrangement if possible, for I do not wish the gun case to be knocked about. Also I should like to know if a gas bag of suitable size can be carried on a motor cycle, by which to drive the engine for, say, ten miles without replenishing? Is it a practical arrangement for successfully driving a motor cycle—for short distances only, of course? Is there any good substitute for petrol which does not require a licence or permit to buy?—ENQUIRER.

The ordinary pattern gun case would be rather bulky to take on the carrier of a motor cycle. The best plan is to make a special waterproof carrier, and attach it in a vertical position to the spring portion of the front forks. It will then be saved a good deal of jolting. There is, however, a gun case which takes far less room than the ordinary pattern. This type is known as the Shikari, and can be obtained from the Army and Navy Stores, 105, Victoria Street, London, S.W.1. This, we think, could be carried lengthwise on the carrier, and if there were a slight overhang at the back it would not matter greatly. We fear that it is not practicable to run a motor cycle from the contents of a gas bag. In the first place, a bag to hold enough gas to propel the machine for ten miles would be very bulky, and also with coal gas the engine would not give so much power as with petrol, and would probably overheat. We are sorry to say that we do not know of a single substitute which can be purchased without being entered on a petrol licence.

### Piston Rings.

**?** (1.) What is the capacity of a 1909 Triumph petrol tank? (2.) Would an engine necessarily have more power with a piston fitted with three rings than two?—H.P.

(1.) The tank in question holds one and a half gallons of petrol. (2.) An engine with two piston rings will be more efficient than one with three piston rings on account of reduced friction. Three piston rings, however, would hold the compression for a longer time.

### Water-cooling.

**?** I have a Zenith-Green. Owing to radiator troubles, I recently sent the copper jacket and cylinder complete to the makers for reswearing, etc. I found, on receiving it back, that the cylinder was apparently a new one, though the clearance when using my old piston in it is about .005in. or so, which I gather should be ample. As a solo mount my bicycle is all that could be desired, the kick and life being remarkable. Now—although I never had any trouble when running with sidecar before the above alterations—it boils up disgracefully at the slightest provocation, losing lots of water. The sidecar is lined up correctly, and the exhaust ports are free and clean, no baffles being used. Circulation takes place in the radiator. Could you please give me any remedy for this trouble?—A.B.

We should say that the trouble is probably due to the fact that the new cylinder requires to be run in for a little time. In due course the trouble should disappear. You say that the circulation takes place in the radiator, but are you quite sure that it is absolutely unrestricted? We think you ought to investigate matters a little more closely and see that all passages are quite free and clear.

### Timing a Small Twin.

**?** I have a 2½ h.p. Moto-Rève twin-cylinder motor cycle, but cannot get it timed up rightly, everything else being in order. Could you advise me as to the best (a) valve timing, and (b) ignition timing for an engine of above make? I have now got it timed as follows: Exhaust valves begin to open when piston is about 2 mm. from the bottom of firing stroke, while the ignition is timed on dead top of compression stroke, with magneto two-thirds retarded. I can only get one muffled explosion every time exhaust valve lifter is dropped. Do I time the ignition to the first or second cylinder?—L.B.

Your valves should be timed as follows: Set the exhaust valve to close just after the completion of the exhaust stroke. It will then commence to open when the piston is about one-seventh of the length of the stroke from the bottom of the firing stroke. The inlet should commence to open as the exhaust closes, and remain open for one complete stroke of the piston, or while the flywheels turn through 120°. We would recommend the following magneto timing: Place the

piston exactly on top of the compression stroke, and connect up the magneto with the points just about to break, and the ignition lever two-thirds retarded. This will mean that the explosion, when the ignition is fully retarded, will take place when the piston has travelled about 1.5 mm. down the firing stroke. Your trouble is probably due to some magneto defect. The back cylinder is probably No. 1.

### READERS' REPLIES.

#### Lubricating the Gear Box.

I noticed in your reply to "T.P.L." that you answer: "Thick grease is quite satisfactory for gear box lubrication"—a fact with which I quite agree, but must point out that the B.S.A. gear box also encloses a multiple plate clutch designed to run in *thin* oil (B.S.A. gear oil), and that the use of any oil thicker than the oil recommended must lead to excessive clutch slip. With my own machine even the use of engine oil turned out a failure and necessitated washing out with petrol (in war time) and filling up with Singer sewing machine oil (gear oil being temporarily unobtainable). Hoping your correspondent does not slip his clutch (and admit the thick grease between the plates thereby).—ALEX. LACEY.

#### Flywheel Loose.

Riders of two-stroke lightweights may like to know that the same thing happened to me as was described by "J.C." in a query of your issue of July 26th. The engine pulled up, owing to the flywheel becoming loose, and could not be restarted until tightened up, when it went right away.—E.P.H.

### RECOMMENDED ROUTES.

# MISCELLANEOUS ADVERTISEMENTS.

## PRICES.

**ADVERTISEMENTS** in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to **ILIFFE & SONS Ltd., and crossed & Co.**

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

## NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000; c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

## DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

## SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

## MOTOR CYCLES FOR SALE.

### Abingdon.

**ABINGDON** King Dick, 3 1/2 h.p., countershaft gears, and sidecar, bought new 28th July, driven 20 miles only; best offer.—Thompson, Potato Merchant, Ipswich. [6354]

## FASTENER FAULTS

If the fault simply ended with the fastener, then they would count for little, BUT—

Seeing that the failure means, perhaps walking miles, perhaps effecting on the roadside that which always must be a dirty repair—in fact, a "hold-up" anyway—it's worth considering which is "The Fastener that never fails."

We make that claim and stand or fall on it.—

Here are two of our models.

The FORWARD, 1/6.

The KING HOOK.

Detachable, 1/-. Adjustable, 1/3.

## DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the production of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

INDIAN Combination, 1915, 5.6-h.p., very little used, and in absolutely top hole condition: £58.—Longman Bros., King St., Acton. Phone: Chiswick 1578. [6317]

5.6-h.p. Indian Motor Cycle, 1915, and coachbuilt sidecar, in good order, and fully equipped, Binks carburetter; £65.—Peelies Motor Co., Ltd., Edinburgh. [X3576]

INDIAN Motor Bike, 1915, 5.6-h.p., 3 speeds, clutch, all accessories, Canelet sidecar, perfect condition throughout; genuine bargain, £55.—Rae, House Cottage, Twickenham. [6262]

1914 Indian Combination, 7.9-h.p., 2-speed, spring frame, electric model, fitted with 1915 kick start, in excellent condition; £55.—Elice and Co., 15-16, Bishopsgate Av., Camomile St., E.C.3. [0492]

INDIAN, 1916, 7.9-h.p. Powerplus Model, Lucas lamps and horn, and special Canelet sporting sidecar, splendid condition; £95 cash, or plus 2% extra for deferred payments.—Wm. Whiteley, Ltd., Queen's Rd., W. [6250]

RIDER TROWARD'S, 31 and 78, High St., Hampstead.—Indian, latest 1916 sporting Powerplus combination, Swan torpedo shape coach sidecar, disc wheel, T.T. bars, 3-speed, clutch, kick start, fully equipped, and as new, 85 gns.; 1915 7.9-h.p. T.T. Indian, 37 gns. [6288]

INDIAN, 1915, 5h.p. model, 3-speed, kick starter, lamps, and new Indian Canelet sidecar, £68/10; also 1915 T.T. 7.9-h.p. solo model, disc wheel, speedometer, lamps, and horn, condition quite as new; £55; closed for the holidays from Monday, August 6th, until Friday, 10th.—Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green. [6301]

## Ivy.

IVY, 1915, 2-stroke, in fine order; £18/10.—The Walsall Garage, Walsall. [X3059]

IVY, 2-stroke, 2 1/2 h.p., 1915, good tyres, fully equipped, as new throughout; £25.—Advertiser, 156, Gt. Portland St., W.I. [5924]

## James.

COLMORE Depot, 261, Deansgate, Manchester, have in stock complete range of James motor cycles. [0803]

JAMES Combination, 1915, 4 1/2 h.p., 3-speed, chain drive, lamps, horn, etc., very good condition; £50.—Wylie, Frating House, Grays. [X3527]

JAMES, 1917, brand new 3 1/2 h.p. twins, two only left; £69/10 cash, or deferred payments 2% extra.—Wm. Whiteley, Ltd., Queen's Rd., W. [6253]

1913 James, waterproof Bosch, chain drive, counter-shaft 2-speed gear, and coach sidecar, body brand new; £36/10.—Motor Exchange, Horton St., Halifax. [6122]

RIDER TROWARD'S, 31 and 78, High St., Hampstead.—James, 1915, 3 1/2 h.p., 3-speed, sporting lightweight combination, 52 gns.; solo, 45 gns.; 1915 James, 4 1/2 h.p., 3-speed, 39 gns. [6289]

RIDER TROWARD'S, 31 and 78, High St., Hampstead.—New 1917 models James in stock for immediate delivery; catalogues free: 2-stroke 2-speed, £40/10; 3 1/2 h.p. twin, 3-speed, £69/10; 4 1/2 h.p. big single, 3-speed, £69/10. [6282]

## The "GRADO" Paraffin Vaporiser.

Motor Cyclists! Here is a device which will enable you to run on paraffin and get results equal to petrol. It is designed by a practical engineer, and has been well tested. It fits between the engine and carburetter, and is connected to the silencer pipe by the clip illustrated. An injection of petrol through the tap on top starts your engine. Paraffin then does the work.

This is the New Model.

PATENT No. 13113.

It is just what you require to-day.

The price, all complete, is **35/-** Postage 6d. extra.

Delivery from stock. Order now, stating the outside size of inlet pipe.

## The "GRADO" MULTI-PULLEY.

PATENT No. 27485/13 and 6612/14.

Is simple in construction. Nothing to go wrong. Fits any standard belt-driven machine. Just half a turn of the handle changes from top gear to free engine. So simple. Starts you like a car.

The low gear gets you through traffic. The high gear saves fuel and gives you speed. The middle gears are there when you want them. The price, complete, for Triumphs, Bradbuys, etc., is **£3 3s.** Ball-thrust model, which we recommend, **£4.** Lightweight models from **£2 10s.** Recessed pulleys, 10/- extra. Postage 2/- extra. Delivery from stock. Write for Catalogue.

Pulley fitted to machine.

## The "GRADO" HEATING JACKET.

PROV. PATENT No. 8124/1917.

This is the simplest and most effective way of heating the fuel. It does the trick in the right place. Simply fits over the carburetter, and allows of hot exhaust going all the way round it. There is no need to heat your fuel two feet away. Do it on the job by the "Grado" Heating Jacket.

Made for A.M.A.C., Senspray, B. & B., Triumph, etc. State diameter of float chamber, or send carburetter and we will return with one fitted. Order to-day.

Price complete is 15/-, post free

**GRADO MANFG. CO.,**  
Presto Buildings,  
Pershore St., BIRMINGHAM.

## MOTOR CYCLES FOR SALE.

## J.E.S.

J.E.S., 1hp., fitted to Raleigh 3-speed; 11 gns., motor complete, without bicycle, £8; condition excellent.—Rev. Brown, Chua, Selcyp. [X357]

## Levis.

COLMORE Depots, Birmingham and Leicester, for delivery of all models of Levis motor cycles from stock. [0880]

LEVIS, 2 1/2 h.p., 1916, 2-stroke, large P. and H. head lamp, generator, rear lamp, mechanical horn, Veeder cyclometer, condition as new throughout; £27.—Advertiser, 156, Gt. Portland St., W.I. [6202]

## Lincoln-Elk.

31 h.p. Lincoln-Elk, wicker sidecar, Hellesen ignition, splendid order; £12/10.—2, Taverners Rd., Peterborough. [X352]

## Mancunian.

MANCUNIAN, 2 1/2 h.p., 2-speed; £33.—W. and J. Motor Co., Ltd., 287, Deansgate, Manchester. [605]

## Martin.

RIDER TROWARD'S, 31 and 78, High St., Hampstead.—Martin-Jap, 6h.p., o.h.v., 1915, new condition, 75 m.p.h. guaranteed; 37 gns. [6225]

## Matchless.

MATCHLESS Motor Cycles; no quicker delivery obtainable than from Colmore Depots. [0888]

LATE 1915 Matchless, 7.9-h.p. M.A.G. engine, 3-speed and sidecar, whole lot is in 1917 condition; offer—785, High Rd., Leytonstone. [634]

MATCHLESS 1915-16 8B 7hp. Combination, with lamp accessories, child's seat at rear, tip-top order; £25; closed for the holidays from Monday, August 6th, until Friday, 10th.—Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green. [630]

## Minerva.

31 h.p. Minerva and wicker sidecar, good condition B. and B. carburetter, Bosch mag., N.S.U. geo £20.—Riddick, High St., Malmesbury. [X355]

## Moto-Reve.

MOTO-REVE, 2 1/2 h.p., mag., spring forks, was tuning; £7.—Rand, Longcross, Surrey. [624]

## Motosacchoe.

1914 3 1/2 h.p. Twin Motosacchoe Combination, kick starter, electric lamps, luggage carrier, etc., driven 1,000 miles; £50; would sell separately.—Can be seen at 8, Bessborough Mews, Westminster, S.W. [635]

## New Hudson.

NEW Hudson, 1913, 3-speed; great bargain, £25.—The Walsall Garage, Walsall. [X301]

1915 New Hudson, 3-speed, clutch; bargain, £38.—Comer, 87, Carrow Rd., Thorpe. [X351]

NEW Hudson, 2 1/2 h.p., 3-speed lightweight, in nice condition; £19/19.—Motor Exchange, Horton St., Halifax. [611]

NEW Hudson 6h.p. Twin Combination, 3-speed, 1914 £60.—W. and H. Motor Co., Ltd., 287, Deansgate, Manchester. [601]

NEW Hudson 1913 Combination, 3 1/2-4h.p., free engine, 3-speed, clutch, good tyres; £28.—Rand, Longcross, Chertsey, Surrey. [621]

NEW Hudson Combination, twin, speedometer, lamp, new spare bolt, tube, splendid condition; £60; near—1, Thorncroft Rd., Brixton Hill. [635]

NEW Hudson, 2 1/2 h.p., 1915, 2-stroke, in very nice order; trial here willingly; very cheap at £25.—Simmonds, Commandant, Military Hospital, Epping, Essex. [X355]

## New Imperial.

NEW Imperial, 1917, 2 1/2 h.p., 3 1/2 h.p., 6h.p. model in stock.—Crow Bros., Guildford. [251]

COLMORE Depots, Manchester and Leicester, for immediate delivery of New Imperial motor cycles. [0888]

NEW Imperial, 1914, 2 1/2 h.p., 2 speeds, good order; £25.—S. G. Misselbrook, Edmunds Farm, Gomsha near Guildford. [X359]

RIDER TROWARD'S, 31 and 78, High St., Hampstead.—New Imperial, 1916, 2-speed, as new; 1915 2-speed, 25 gns. [621]

NEW Imperial-Jap, immediate delivery all models. Exeter Motor Cycle Co., Ltd., Bath Rd., Exeter and Tavistock Rd., Plymouth. [09]

NEW Imperial-Jap, 1915, 2 1/2 h.p., 2-speed, head lamp, generator, rear lamp, all accessories, good tyres, fully equipped; £25.—Advertiser, 156, Gt. Portland St., W. [59]

NEW Imperials, 1917 models, for immediate delivery No. 1 39 gns., No. 2 46 gns.; two new 1916 models No. 1 at £38.—Colmore Depots, 211, Deansgate, 31, Renshaw St., Liverpool. [088]

NEW Imperial-Jap, 2 1/2 h.p., 2-speed, variable ignition, Stewart speedometer, aluminium footboards, no lamps, good tyres, just re-namelled, and in perfect running order; £26, no offers.—Childs, High St., Peterfield. [62]

## Industrial Alcohol.

**L**AST week, when referring to the fuel question, we touched very briefly upon the use of alcohol in internal combustion engines. On another page of the present issue will be found some notes on the same subject, culled from a most interesting treatise which deals with the production and use of alcohol for industrial purposes.

The whole subject is one of intense interest, because alcohol can undoubtedly be used as a motor fuel, and though, in its present form, it does not give the same results as petrol, it possesses these great advantages: that it can be produced at home, and consequently, in such times of stress as now obtain, when it is desirable to restrict imports as far as possible, it could, if available, allow everybody to motor without let or hindrance; that its production fosters industry of all kinds, benefiting the manufacturer and also the agriculturist. Alcohol is a fuel of which there is an unlimited supply, while it is an acknowledged fact that petrol is not inexhaustible, neither is benzole nor the coal from which it is produced. The fact that water can be added to the alcohol without stopping the engine is a most interesting one. It would not, of course, increase the thermal contents of the fuel, but it might very conceivably improve the consumption, because a certain amount of heat which under ordinary circumstances is useless, or even worse than useless—for we have to devise special means to get rid of it—would then be used in converting some, at least, of this water into steam, which would in its turn do useful work. Experiment has shown that the addition of water vapour to the mixture improved an engine for sidework by rendering the explosion less instantaneous. The sole deterrent to the manufacture of alcohol is that its sale is so hedged about with restrictions and taxes lest people should drink it that until these are removed it is useless to expect that any development in its production can take place.

## The Youngest Despatch Rider.

**T**HIS week we devote space to a question which, judging by the number of letters received, has created considerable interest. To those loyal youths who succeeded at such early ages in enlisting as despatch riders and so becoming important cogs in the wheels of our intricate war machine, we offer our congratulations. No doubt to them and to their parents there is pride in the mere fact of their serving, quite apart from the high motive that inspired them. But there is another feature about this eagerness and enthusiasm that is worthy of thought. Underlying the unquestionable patriotism there is the love of adventure and a love of the motor cycle, and, more likely than not, a zest for mechanics. We must therefore have among D.R.'s the very finest material from which to make air pilots. "Find them young" is the frequent cry, and surely, in view of the vastly growing Air Service demands, many embryo aviators could be culled from the great army of D.R.'s. It is not for us to say whether the supply of pilots is greater than the demand, and whether or not there are plenty of men ready for training, but it can truthfully be stated that there are potential pilots by the thousand among these young despatch riders, while many of the original riders are already serving in this capacity. Yet we know of many cases in which capable motor cyclists, after long service in France, have expressed their eagerness to obtain commissions, and, nothing else forthcoming, have accepted commissions in infantry units. This seems to us a misuse of good material, for in the motor cyclist is found the essence of what is required in the flying officer, and there ought to be no difficulty placed in the way of those whose ambition and training especially adapt them for this branch of the Army.

There is at present, however, as the majority of D.R.'s know, a good deal of red tape to unravel before a commission can be obtained in the air service.

# IDEAS: Useful and Ingenious.

Gray Rees

## FOOT-CONTROLLED CLUTCH.

AN easy way of adapting a counter-shaft gear so that the clutch may be operated either by hand or foot is shown in the accompanying sketch. It will be seen that an arm is fitted

Foot-control, in addition to Bowden control, of a Sturmey-Archer clutch.

with a toggle, and by this means the clutch can be operated effectively with the heel, the Bowden control, of course, still being retained.—M.G. (M.T.), Rouen.

## VALVE CLATTER ON A DOUGLAS.

THIS somewhat objectionable complaint does not usually occur with the inlet valves, but it does with the exhaust in consequence of the extra clearance. I first tried springs placed under the tappets, but these did little good, as the noise still persisted through the ends of

Reducing valve clatter on a Douglas.

the rockers hitting the ends of the tappets inside the crank case. Finally, I hit upon this plan. Obtain from a Meccano stockist two spiral springs. These are just right for the job. Drill and tap a small hole in the side of the crank case,

Readers of "The Motor Cycle" are invited to contribute to this page any ideas successfully adapted to their motor cycles. Rough sketches will suffice.

as at A. A small screw is fixed in here. One end of the spring is fixed to the exhaust valve rocker by two or three turns of strong copper wire, and, if desired, the wire can be sweated in place. The other end of the spring is fixed to the small screw—A. It is surprising what a difference this little alteration makes to the noise. On my machine there is now no noise at all from the valves.—G.F.J., Sheffield.

## AN EASILY-MADE UNDER-SCREEN.

AN underscreen is a very useful fitment, especially on a motor cycle which is used in all weathers, but, curiously enough, it is found as standard on very few makes. It is, however, generally easy to construct and fit one at home, and very few tools are required. A piece of sheet iron forms the principal part of the screen—what is known erroneously as tin is hardly stout enough, while brass or copper, though excellent, is expensive. Two pieces of wood are

A simple home-made underscreen.

tightly screwed to the sides, not so much to add strength as to prevent rattle, and pieces of strip iron are riveted to the ends. The attachment blocks should be made of some hard wood which is not likely to split; ash or walnut will do admirably. First, a hole is bored through which the footboard support can be pushed (the tighter this fits the better). A saw-cut is then made longitudinally through this hole and some little distance beyond, and the blocks clipped in position by means of bolts and nuts. The bolt will often have to be below the crossbar, but the fitting will be

sufficiently secure. Lastly, the ends of the strip iron are screwed to the blocks and the job is complete.—AURIGA.

## SADDLE SPRINGING.

THE accompanying idea has been sent to us by a New Zealand reader, who says that he has seen it used on an Enfield, and that the leaf springs give a motion which can be equalled by only one spring frame machine which he has tried, namely, the A.B.C. The springs are 1½ in. in width and a little

The dotted portion of this saddle frame is sawn off and replaced by leaf springs firmly attached to the top of tube and clipped together in the centre.

more than ¼ in. in thickness. The length of the springs depends upon the weight of the rider, and must be found by experiment. Our correspondent, R.E.H., assures us that the device is so satisfactory that it is well worth the trouble of careful fitting.

## A LOCK FOR MOTOR CYCLES.

THE best lock for a motor cycle I have come across is a brass kitbag fastener which is put round the bell rim and back stays. The padlock is a

An effective method of locking a motor cycle.

Yale, and can be procured at any ironmonger's for 5s. The fastener is procurable at officers' equipment depot, and costs 1s.—F.C., Carr. (Bootle).

## In Memoriam.

WE have all of us lost many old comrades of the road in this war, but no motor cyclist could be so widely missed and mourned as Ivan Hart-Davies—"H.D." as many of us affectionately called him. Fine rider as he was, we demand more than sporting ability in a pal, and Hart-Davies owed none of his many acquaintanceships to the fact that people love to hobnob with a celebrity. The simple fact is that he was one of the friendliest of men. His manner was the same towards everybody: and he was just as frank and good-natured to some chance stranger on the road who chanced to recognise him from press photographs, as he was to his usual companions. He made many friends, forgot none of them, and, to the best of my belief, lost none. He commenced speed work at an age when most men have lost the nerve for it: but in sustained speed he had no rival on the road. There were plenty who could hold him for an hour or two, and some who could temporarily outstride him: but nobody could keep going at a high speed as long as he, nobody could keep the same dash and restraint unimpaired after a long day or a long night in the saddle. He was game to the last. He had fretted over the probability that his age would keep him on home service flying; and he was as gleeful as a schoolboy on holiday when he was notified that work Overseas lay ahead of him.

## In Reply to "Wharfedale."

I WONDER much what "Wharfedale" is in civilian life: he does not seem to comprehend the uses of advertisement. Between the Scylla of over-boosting the flat twin, so that it risks being laughed off the earth by an infuriated public, and the Charybdis of leaving its merits to be appreciated by a few cognoscenti, he leaves me no middle path, and does not even see that my supreme egotism was one last appeal to his vaunted sense of humour. However, let us tackle more technical matters. His stern criticism of the flat twin is apparently based on A.S.C. workshop experience of a thousand machines. This being so, his technical condemnation is based on a single make. There was once a famous traitor who said that you knew what all Greeks were like, if you had met one: and there have been business firms who passed large contracts on the inspection of a single sample. But the traitor, if he were not fabulous, has been dust and ashes some thousands of years, and the firms filed their petitions before the war. So I will seek a parallel more germane. There was once a W.D. motor cycle which had a spring on its fork, and the aforesaid spring proved unequal to the demands of public service. Now large fleets of these machines passed through a base workshop, in charge of which was a highly efficient and extremely likeable engineer named Wensleydale. Mr. Wensleydale was an excellent engineer, but a poor logician, and, falling into an argument on fork springs, he delivered himself of

the verdict that all fork springs either were bad, or would not be much use for at least another ten years: whereby he tickled the groundlings mightily, but failed to convince the universe. Yet, gentlemen, there is something repellent about logic in these days—a taint of Prussianism, methinks. Let us seek light in a gentler sphere—what do the poets say? Was it not Tennyson who sang:

"'Tis better to have 'revved' and seized  
Than never to have 'revved' at all."

## The Four-cylinder Engine.

BEDELL'S ride on the Henderson has revived my interest in the possibilities of four cylinders. In many respects it resembles the flat twin from a practical standpoint. It offers perfect balance, a great range of speeds varying from furious r.p.m. down to the merest tick, and a very pleasant exhaust note: and these are the hall-mark of the flat twin. The four-cylinder is the more expensive to make, and the more difficult to provide with an adequate flywheel, seeing that its flywheel must revolve athwart the track, and so is not easy to construct for really slow running, whereas the F.T. flywheel runs in the line of the track, and may be of fair diameter. Again, a water-cooled flat twin would make a particularly uncouth engine: but a water-cooled *monobloc* four-cylinder would make a jovial little power unit for the post-war super-sidecar, and would lend itself admirably to the unit type of gear box and the shaft drive. The Henderson record undoubtedly means that it is possible to construct at a commercial price a four-cylinder machine free from the petty troubles and frequent adjustments which rendered the old fours undesirable mounts for the inexpert. If I were a manufacturer of sidecar outfits *de luxe*, I should certainly get out an experimental four-cylinder. Of all abominations the big V twin is the worst, to my thinking, though it has been, and still is, an uncommonly useful makeshift. It blocks up the entire frame, and is inaccessible. We have got to advance beyond it, and that soon, and for high powers and sidecars the four-cylinder might well be its worthiest successor.

## Another Great Ride.

IF anybody had told me that mortal man would ever ride round the clock on a motor bicycle at an average speed of nearly fifty-eight miles an hour, including all stops, I should have scoffed at him: and if my opinion of things American had not been transformed by their unexpected pugnacity towards Fritz, I do not know that I could quite believe it now. "Cannonball" Baker's ride was some stunt so far as the Indian machine is concerned, but the mechanical aspects pale by comparison with the tough tenacity of the rider. I begin to think we shall see some spring frames out in the next T.T. ["Cannonball" Baker's record has been eclipsed, as reported in this issue.—ED.]

# DARTMOOR AS A TOURING GROUND.

SOME ACCOUNT OF THE  
ROADS, BEAUTIES, AND  
ANTIQUITIES OF SOUTH DEVON.

By H. TAPLEY-SOPER.

THE "Forest of Dartmoor," as it is described in ancient documents, generally calls up visions of impossible roads, bogs, fogs, escaping convicts, and, perhaps to the more romantic, "pixies" (the local name for the little fairies who are supposed to dwell in parts of the moor). For the fairies we cannot vouch, fogs seldom occur in the summer months, and bogs need not trouble motorists who are content to stick to the main roads, which generally have good surfaces, and pass through some of the most majestic scenery to be found in England.

Escaped convicts are almost entirely confined (no pun intended) to the fertile imagination of novelists. We can only recall two successful attempts during the past fifteen years, and in each case liberty only extended over a few hours. Such attempts are invariably made in autumn when fogs, which are not of the black variety known to Londoners, but a whitish, rolling mist, suddenly spring up and envelop patches of a few miles in circumference, and which can be easily escaped by the exercise of caution and commonsense. Moreover, the authorities, apparently anticipating the wishes of, at any rate, lady motor cyclists, have recently removed all the convicts from Dartmoor and given up their quarters to that curious hybrid, the conscientious objector.

Any guide book will inform those interested of the numerous objects of antiquity which the moor possesses—the stone avenues, sacred circles, cairns, kistvaens, cromlechs, logan stones, and rock basins—many of which to this day remain as something of a mystery to the antiquary and historian.

Roughly speaking, "Dartmoor," as it is pronounced by the old moor-men, is about twenty miles square, and, except in the wooded and inhabited bottoms, consists of a huge igneous upheaval of granite, covered only by a thin mantle of peaty moss. Its general appearance has been aptly described by an American tourist as "bosomy." In some places bare rocks rise to great heights. These are known as tors, the highest being High Willhays, which is 2,039 feet above sea-level. Heather and ling flourish here, and large patches of glorious golden furze or gorse brighten the moors during the summer months and add to its fascinating colour effects.

The author and his friend, with the A.J.S. combination, on which the tour was accomplished.

We learn from "Domesday" that in the time of Edward the Confessor Dartmoor was of the King's *demesne*. Its description as a "forest" is a mediæval euphuism. The extensive tracts of land in different parts of the country called Royal forests were appropriated for preserving animals of the chase, but they were not necessarily covered with wood in all parts, but just had sufficient in places to afford shelter and cover. Since 1337 the Forest of Dartmoor and its belongings have been permanently annexed to the Duchy of Cornwall as an appanage of the Prince of Wales. Doubtless our readers have recently seen accounts of the proposed attempts which have been made by the Duchy authorities to reclaim certain tracts of land for agricultural and cattle rearing purposes. Excepting hares, rabbits, and a few foxes, there is now nothing on Dartmoor to hunt, but the many streams which feed the county's principal rivers provide good fishing and wild fowl. The small and hardy Dartmoor pony which breeds here in a semi-wild state is well known, and the pasturage, although scanty, sustains during the summer months fairly large flocks of sheep.

## The Dartmoor Roads.

Situated on the outer circle of the moor are the towns of Okehampton, Moretonhampstead, Ashburton, and Tavistock. These are connected across the moor by well engineered main roads, which it is the purpose of these articles to introduce in detail to motor cyclists who, when visiting Devon, often miss her most unique features under the impression that Dartmoor roads are mere cattle tracks and precipitous hills. The writer has on many occasions been over all the routes described with a sidecar and passenger on a  $3\frac{1}{2}$  h.p. Lea-Francis, a 4 h.p. A.J.S., and a 6 h.p. A.J.S. The latter, with standard sidecar, is his present outfit. His riding weight, to use a turf expression, is 13 st. 6 lb.

A plan of one of the many Dartmoor hut circles. Several early writers wrongly connected these curious ruins with the Druids

**Dartmoor as a Touring Ground.—**

and his usual passenger, who has supplied the photographs for these articles, turns the scale at a little over 12 st. The outfit, with spare wheel and other paraphernalia, weighs  $5\frac{1}{2}$  cwt.

Having done 5,000 miles with this combination with only two punctures the spare wheel is now carried as a charm against punctures rather than as a substitute for such calamities. It must not be supposed from these remarks, however, that motor cycling on Dartmoor is quite such a simple matter as bowling along through the New Forest; there are some severe gradients and some tricky curves to negotiate, but these will not call for more than ordinary care and skill from experienced drivers mounted on reliable machines. Off the main roads there are some real terrors, but the routes now described are suitable for the motor cyclist with his wife—or somebody's sister—in the sidecar.

Leaving Exeter, which is an admirable centre for all parts of Devon, you proceed down Fore Street, which is steep, narrow, and "trammy," and with due caution shoot across Exe Bridge and up a short nap called Dunsford Hill, and having descended on the other side—as you will mount and descend many such hills during the day's journey—you select by the aid of a signpost

wide curve on a steep gradient, which should be treated with respect and taken on second gear. The church is on the right just past some picturesque early seventeenth century almshouses which will be noticed at the top of the hill. Until a few years ago there stood in the centre of the town at the cross roads a large tree known as the "dancing tree." It was kept cut so that its branches stretched out level and supported a platform upon which, on festive occasions, dancing took place. In 1807 a band composed of French prisoners of war from Princetown gave a concert on the dancing tree. In the churchyard can be seen the tombstones of some of these prisoners who died here while on parole.

The river Teign in draught—a picturesque scene near Steps Bridge, Dunsford.

Blackingstone Rock, Moretonhampstead, 1,127 feet above sea-level.

on your right the Moretonhampstead Road. The whole of this road is somewhat restricted and twisty, and should be taken at a moderate speed, which will allow of due admiration of the beautifully wooded surrounding country.

About seven miles out, at a picturesque point, the river Teign is crossed by Steps Bridge. This is a favourite short run from Exeter for an open air tea and a scramble along the banks of the river which offers much of interest, whilst in the village of Dunsford near by is an old church, the tower of which can be seen from the bridge.

Moreton, to use its usually abbreviated form, is about six miles further on, and is approached by a

At Moreton in 1806 George Bidder, the rapid calculator and well-known engineer, was born. His reputation was so great that on one occasion when engaged to give evidence in a law suit the opposing counsel asked that Bidder should not be allowed to remain in the Court, on the ground that "nature has endowed him with qualities that do not place his opponents on a fair footing." The Moreton people claim that Bidder's intellect was due to the clear air and invigorating breezes which this old moorland town enjoys, showing that in those days the exhilarating effect of high altitude was recognised.

**Blackingstone Rock.**

About three miles from Moreton is a well-known Dartmoor tor—Blackingstone Rock—from the summit of which (1,127 feet above sea-level) a most magnificent view is obtained. Steps have been cut in the rock and a rail provided for those who care to venture to the summit, where a cool and refreshing breeze can be enjoyed on the hottest summer day. Another pleasant after-lunch ramble, which must be taken on foot, is to Mardon Down, which is about a mile from Moreton. Proceeding by way of the road on the north side of the church take the left-hand branch at the fork. About a quarter of a mile on the right soon after

### Dartmoor as a Touring Ground.—

reaching the down are the remains of a cairn known as the Giant's Grave; a local tradition says:

"Here beneath this great tall stone  
Great Maxi Magur lies,  
And if you goes at twelve of night  
You'll hear most awful cries."

Tor is the name given to the imposing masses of granite which surmount many of the hills, and which are amongst the most striking features of the scenery of Dartmoor. The word is said to be derived from the Celtic "twr"—a tower, which appeals as highly probable, as from below one gazes up at these lonely and stately formations and recalls what the geologists tell us of their former lava state from which they were uplifted by the forces of nature to solidify and remain in solid grandeur as sentinels of the moor. Blackingstone Tor is the finest in the Moreton district, but the western and eastern sides of the moor provide grander and more numerous specimens. Their summits are visible for miles before the moor is actually reached, and the motorist bound for a trip across this district should note them as he approaches. Each tor has a name, as Fur Tor, Mis Tor, Yes Tor, Saddle Back Tor, Hey Tor, etc., and each possesses distinctive features or contours which after a while can be easily distinguished from a considerable distance. The mists which often surround the summits of the tors in the early morning and late evening add greatly to the colour interest and provide most gorgeous and sometimes weird sunrise and sunset effects.

### Grimspound.

The Blackingstone Rock and Mardon Down excursions are off the main road, and are introduced for those who do not care to follow us on to Tavistock, the farthest point aimed at along this route. Another deviation would be to Grimspound, the most notable of the Dartmoor hut circles. After passing through Moreton, take the sixth turning on the left. A mile and a half along this road will bring you to a bend

on the left, where you must dismount for a scramble up over a rugged escarpment, down which runs a little stream of water—the stream which supplied the inhabitants of this prehistoric encampment which we have come to view. The actual circle is about a quarter of a mile from the spot which we have indicated. Most of the stones with which it was built still remain, but only a small proportion are now *in situ*. They originally formed two irregular circles, one within the other and about three feet apart, and are estimated to have risen to about five feet; they enclosed about four acres. The antiquaries are of the opinion that, whatever was the original purpose of its builders,

the place was never finished, and was merely used as a temporary summer camp and cattle pound by the inhabitants of the valleys, who drove their cattle up for summer feeding. The contention of the earlier writers that Grimspound was connected with Druids, or was a fortified village, is now generally discredited. The surrounding walls served the purpose of a cattle pen and a protection against wild animals. Within the pound are twenty-four hut circles. One, enclosed within a railing, has been partly restored to show visitors what form these early habitations took. The raised dais, it is presumed, formed a seat by day and the owner's bed by night. The walls of these huts were four or five feet high, and are said to have supported a roof probably composed of turf, rushes, or heather.

Some flint implements have been found in these enclosures, also pot-boilers or cooking stones, and cooking holes containing charcoal, which prove that the huts were inhabited at a very early date. Many of the slabs of stone used in the walls are quite large, and one particularly hefty fellow is estimated to weigh nearly four tons. From the fact that no evidence is forthcoming that the people who used Grimspound were acquainted with metals or pottery, it is concluded that they belonged to the early Neolithic Age, which, according to geological time, was the period somewhere about 1500 years B.C., but in this antiquarians differ in opinion.

(Top) Curious seventeenth century almshouses at Moretonhampstead.  
(Bottom) Two Bridges, near Tavistock. It is this district that Eden Phillpotts takes as the scene of several of his famous novels.

## Dartmoor as a Touring Ground.—

**An Ancient Custom.**

Retracing our tracks to the main road, we turn left and proceed along the Princetown and Tavistock road through miles of typical moorland scenery. At about three miles we can pass one of the moor's isolated hostelries—the Warrenhouse Inn. The previous night, if the tourist tarried at Exeter, he may have recalled Gray's elegy when at eight o'clock he heard the Cathedral bell tolling.

"The curfew tolls the knell of parting day."

At this inn still lingers the custom of covering the fire on retiring to rest, very much in the manner said to have been ordered by William the Conqueror. The fireplaces in all the old Dartmoor buildings are of the solid and spacious variety, in which the fuel, which comprises logs or lumps of peat "vegs," as they are called, is burnt on an open hearth. When mine host of the Warrenhouse Inn retires to rest he rakes the hot embers together and protects them with a "covrefeu" or a fire cover. In this way the fire is kept burning or smouldering during the night, and requires only to be stirred and fed in the morning; fires have in this way been kept continuously burning for years.

From the Warrenhouse to Two Bridges is seven miles, a stretch of safe road for those who wish to indulge in a speed burst. Two Bridges can be seen in the valley as you speed down the hill; on nearing it the road from Ashburton debouches on the left. Here the driver should get his mount well in hand to negotiate the steepish left-hand curve, upon which other traffic is usually encountered—often on the wrong side. The Two Bridges Hotel is perhaps the best known of all the moorland houses. It is a favourite resort of anglers and tourists. It has a very comfortable lounge which always reminds one of a ship's-saloon. If a ramble in this district is sought, enquiries should be made for Wistman's Woods, one of the freaks of the moor, or for Crockern Tor—one

of the moor's historic spots. On this tor, in the early days, the Parliaments of the Stannary Towns met. We shall have more to say about this unique legislative body when we are on the tour which passes through Ashburton.

**Tavistock.**

On passing over the bridge opposite the hotel a choice of roads is presented—the direct one goes to Princetown, the right-hand swerves to Tavistock. Princetown will be our objective on another tour and from a different direction; to-day we are labelled Tavistock, which is nine miles further on along a stretch of main road.

As Tavistock is approached Kelly College is passed on the right, and further on is the famous Drake statue by Boehm, a replica of the one on Plymouth Hoe. The Great Elizabethan Navigator was born at Crowndale, near Tavistock, in 1542. The town of nearly 5,000 inhabitants is pleasantly situated, and provides a good centre from which to tour this part of the county. It is fifteen miles from Plymouth and thirty-four from Exeter. The remains of the Benedictine abbey, founded by Ordulph in 966, are its principal antiquarian feature. The former magnificence of this abbey can be judged from portions which still exist, parts of which are embodied in the Bedford Hotel and the surrounding buildings. It was at Tavistock Abbey that the fifth printing press to be set up in England was established in 1525.

The church, which dates from 1318, is a large and interesting one; in it is a glass case containing what is said to be the thigh bone of Ordulph, the founder of the abbey, who was a man of great stature. The town has produced many famous men, including William Brown, the author of "Britannia's Pastorals," and the famous lawyer, Sir John Maynard, who was born in 1602 and lived to a great age. When he was presented to William of Orange, at the age of eighty-seven, the King remarked that he must have outlived all the judges and eminent men of his day.

"Yes," replied Maynard, "and I should have outlived the laws too, had it not been for the happy arrival of your Majesty."

◆ ◆ ◆

[The above article is the first of a series in which we hope to describe various parts of England and refer to interesting places and objects which are not all to be found on the main roads. It will be followed by further descriptions of Dartmoor by Mr. H. Tapley-Soper, and later we propose to visit other districts. Although at the present time touring by motor cycle is out of the question, we feel that, while motor cyclists exist, the spirit of the open road will never be extinguished, and if we are able to suggest trips which can be taken in happier days our object will be accomplished.—ED.]

**HELPFUL BUT RISKY.**

Pillion riding is child's play compared with the above dangerous practice of giving a helping hand. No doubt the action was appreciated but the danger is real.

## COOLING THE ENGINE INTERNALLY.

Some Criticisms and a Suggestion.

**T**HIS subject appears to have been rather hastily thought out. The first great objection which does not seem to have been foreseen by the writer of the article published in the July 19th issue is that in the four-stroke engine during the compression stroke the ascending piston will draw a full charge into the crank case, and at the same time by lowering pressure in the neighbourhood of the jet cause petrol to overflow. On the down stroke immediately following, the air drawn into the crank case will be discharged, together with any oil, petrol, etc., that may be caught up. Another objection is the great amount of resistance brought into the induction pipe, if the air is properly filtered of grit, etc.

Regarding oil fog, there is this remark: "A certain amount of oil fog would be drawn into the engine which is not without its use." In view of the experience of two-stroke users, it is to be feared that an excess of oil would be drawn into the engine, thus introducing one of the minor evils of the two-stroke into the four-stroke engine.

A contributor's suggestion for cooling an engine internally.

Again, it must not be forgotten that in making the piston into a pump with the crank case as receiver extra work is being put on to the engine at at least three strokes out of four.

With regard to the troubles which the suggested arrangement is expected to reduce, these are clearly stated at the commencement of the article.

### The Conservation of Heat.

Now the crank case is the coolest part of the engine. Further, the amount of heat which can be taken from the crank case, little as it is, will be transferred to the cylinder. This itself is not necessarily an evil, for as it is a heat engine which is under consideration, the more heat which can be conserved the more efficient will be the engine—all this provided that the very conservation of heat does not raise insurmountable difficulties in the mechanical working of the engine, e.g., excess temperature in neighbourhood of piston, consequent bad lubrication, etc. The great fact remains, however, that the evil of excess of heat is felt in the cylinder and piston; it therefore would seem on the present showing that the proposed

arrangement will have little effect in diminishing this. If it were possible to reduce the heat at this point to a working maximum and at the same time conserve the heat which is conducted away a saving in petrol would be effected; or, to put it more correctly, the engine would be more efficient and flexible.

### Air through the Gudgeon Pin.

As destructive criticism is not very encouraging to progress, I enclose a sketch showing a method of "internal cooling" which, I think, has its attractions. This was the outcome of reading the article by "G.S."

The suggestion is, as will be seen from the sketch, to have a hollow gudgeon pin and draw the air through this. There are two positions in which the carburetter may be placed: (1.) Carburetting before passing air through the gudgeon pin. (2.) Carburetting after passing air through the gudgeon pin. The first is a no-trouble position; the second introduces slight complications.

The induction stroke would be rather different from ordinarily owing to the fact that there would be no movement of mixture into the cylinder until the hollow gudgeon pin registered with the ports in the cylinder walls. Carburation would be improved by this method, although it is by no means certain that as great a volume of gas would get into the cylinder at high speeds.

ENGRO.

**RERE CROSS (WESTMORLAND).** Situated on the highest range of this tableland, about seven miles from Brough, Westmorland, is the Rere or Roi Cross, as it is commonly called. It was here, after centuries of bitter warfare, that the kings of England and Scotland met to decide the boundary of the two kingdoms, and so raised this, the "Cross of Kings," on which were engraved the images of the two monarchs. The motor cycle is a B.S.A.

## THE YOUNGEST D.R.

Since publishing the letter from Mr. Roughley, in which he questioned whether his son was the youngest D.R. serving abroad, many photographs and letters have reached us from young D.R.'s who aspire to that honour. The following are a few received on this subject, and are interesting as showing the enthusiasm and loyalty of these young motor cyclists, who enlisted voluntarily to serve their country at the very beginning of hostilities.

### IN THE SECOND BATTLE OF YPRES.

"WITH reference to the query which appeared in your valued paper regarding the youngest D.R., I beg to submit the name of a D.R. who, I think, will stand a good chance for the honours. He is Cpl. Speedie, and was attached with many more of us for duty with the advanced headquarters of the corps during the second battle of Ypres in April and May, of 1915. During the engagement he was sent down to the base, not on account of his lack of pluck, but on account of his age, which was only slightly over 16.

"He was previously attached to the army headquarters, and any of the old D.R.'s will remember him as being a plucky chap.

"I would just like to add that your paper is still full of information, and interest for any of the old M.C. brigade, and was eagerly sought after while we were in France.

"R. S. COLLINS, LT., R.F.C."

### AT YPRES AT 17½ YEARS.

"ALL honour to our gallant young Englishmen of the type of W. Roughley, spoken of in your issue of July 19th. Still, his record of age is easily beaten by my boy, E. D. Osgood, R.E., and I expect by many others.

"My son was at the Second Battle of Ypres as a D.R. at the age of 17½ years, and he was

Cpl. E. D. Osgood, R.E.

one of the very few who were fortunate enough to get round 'Hell's Corner' on that terrible night, and they all deserve the very best we can think of them.

"EDWIN OSGOOD."

### FOREIGN SERVICE AT 14 YEARS 11 MONTHS.

"REFERRING to the paragraph on page 65 of a recent issue of *The Motor Cycle*, I am afraid Mr. Roughley's son cannot claim to be the youngest despatch rider on service.

F. J. Hollis, D.R.

In this connection I may mention that my son enlisted in December, 1914, a fortnight before his fifteenth birthday. He sailed for India within a week of his enlistment, and spent his birthday at sea, somewhere near the Suez Canal. After two years' service in India he left for active service in Mesopotamia in December, 1916. Since then he has been acting as despatch rider attached to a Signal Squadron, and is now 17 years 7 months old.

Mr. Roughley, however, can be proud of the fact that his son is one of that gallant band of lads who rushed to arms when their country needed them without waiting to be fetched, or filling the air with their shrieks about 'indispensability' or 'conscience.'

"B. W. HOLLIS."

### DESPATCH CARRYING IN FRANCE AT 15 YEARS 8 MONTHS.

"WITH reference to Mr. Roughley's question in *The Motor Cycle* of July 19th, 1917, as to who is the youngest D.R. in France, I should like to mention the name of K. O. Bathgate of the R.F.C., who is riding with me. He came to France in November, 1915, at the age of 15 years 8 months, and has been carrying despatches from that date until the present day.

"W.H.W., R.F.C."

### ON ACTIVE SERVICE 2 YEARS 7 MONTHS.

"MR. ROUGHLEY'S query as to the youngest despatch rider should bring forward some interesting information respecting ages at which our boys voluntarily accepted service for their King and country.

"I would mention that my son, Cpl. Richard W. Wright, R.E., enlisted in November, 1914. He went to France on New Year's Day, 1915, at the age of 17½ years. He is still a D.R. in the section to which he was originally allotted on going to the Front, and it will therefore be observed that he has two years and seven months active service to his credit.

"RICHARD J. WRIGHT."

A further selection of letters and photographs from young D.R.'s will appear next week.

Cpl. Richard W. Wright, R.E.

A Douglas motor cycle, an old sack, and a few boxes have been utilised by the ever adaptable D.R., to provide shelter from the terrific heat of the Mesopotamian sun. The scene is between Bagdad and Samarra.

#### SERVICES RECOGNISED.

**A**MONGST the names of those brought to the notice of the Secretary of State for War, for valuable services rendered in connection with the war, is that of Capt. A. J. Palmer, H.B., M.G.C., who joined the ranks of the No. 5 Battery of the M.M.G.S. in the early days of the war, previous to which he was assistant cashier to *The Motor Cycle*.

#### MOTOR CYCLISTS IN THE R.F.C.

**A**RACING motor cyclist, Mr. F. J. Pigot Disney, a member of the B.M.C.R.C., Surrey M.C.C., and other clubs, together with Mr. Baldwin, the Matchless rider, have joined the R.F.C., and are training as pilots. Disney has received his commission, while our informant, Sec.-Lt. Vernon Gayford, R.F.C., who is well known in Surrey motor cycling circles, has also received his commission in the famous corps.

#### AN ALL-ROUND SPORTSMAN.

**T**HE late Lt. Ivan B. Hart-Davies, whose obituary we published in the issue of August 2nd, we have shown to be an excellent all-round sportsman. However, it was not mentioned that among his various accomplishments he was an expert on the bob-sleigh, and in 1913, with three other motor cyclists who had never indulged in this sport before, he won the Murren Cup. It is also interesting to relate that he took to flying before the war, as an amateur.

#### HELP OF THE TANKS.

**I**N the recent big attack in Flanders the Tanks again played a great part in capturing the pestiferous nests of machine guns. Philip Gibbs says: "Many Tanks have gone forward with our infantry, sometimes in advance and sometimes behind, according to the plan of action mapped out for them, and have done better than well against several of the enemy's strong points, where, for a time, our men were held up by machine gun fire."

Mr. W. Beach Thomas also speaks of their great help: "The general progress of the battle was of this nature: The northern half of the attack was a little

earlier than the southern. Our men and some of the splendid French troops alongside them went over the parapet just before 4 a.m. In threequarters of an hour we had advanced 1,000 yards to the first halting place, in spite of the necessity of building and crossing bridges under fire. Soon after five o'clock we and the French started on a further adventure, and again every unit swiftly reached its mark. There was hard fighting at three places, but all were won, one of them by three Tanks."

The *Motin's* correspondent states that the Tanks covered themselves with glory. One of them attacked a concrete redoubt, every man in which surrendered, while in another a Tank made for a spinney bristling with machine guns, and so crushing was the effect of the Tank's advance that there was scarcely a stick left standing, and the entire garrison surrendered.

#### ARMY AND NAVY PAY.

**R**ECENTLY sixty or so Members of Parliament met at the House of Commons to consider the question of sailors' and soldiers' pay. Mr. O'Grady said that where British battalions were brigaded alongside Colonial troops, the Britisher could only deplore the disparity which gave him one-sixth the pay received by the Australian and New Zealander.

The Management Committee suggested that the minimum net allowance to any British soldier should be 3s. a day, and that the Government provide and pay all allotments to wives and dependants.

Lieut.-Col. Wilson, M.P., advocated equalising the pay of sailors and soldiers, and said it was a scandal that men nearest the trenches got the worst pay of all. Infantry men were the worst, then in order came the Artillery man, A.S.C., Ordnance Corps, and the Labour Battalion, until they got to the War Office, where they got the best pay of all.

#### MOTOR CYCLE TENNIS CHAMPION KILLED.

**S**GT. J. E. H. ZIMMERMANN, of Bromley, the International tennis player—whose death at a German field hospital, after being reported missing, is notified—like many other tennis players, owned and used a motor cycle. He joined the H.A.C. last year as a private, and was a member of a big chemical firm.

#### A GALLANT MOTOR CYCLIST.

**T**HE death is announced on the battlefield of Sec.-Lt. Neville Ernest Baker, who was killed on July 31st. He was educated at Clifton College and Trinity College, Oxford, where he joined the 'Varsity O.T.C., and on the outbreak of war became a motor cyclist despatch rider with the rank of corporal, R.E. Signal Service. He went to France with the original Expeditionary Force, served as a corporal through the campaign, including the retreat from Mons and the battles of the Marne and Aisne. In January, 1915, he was given a commission as Temporary Second-Lieutenant, R.E. Signals, and, after receiving further training in England, he again went to the Front in November, 1915, as Brigade Signal Officer. He was recently appointed to the Tank Corps as Signalling Officer, and was killed by a shell while inspecting a wireless installation he had erected. He was a most efficient officer, and was spoken of very highly by his C.O.

A French despatch rider emerging from "Poste de Commandement" of the hidden artillery in a stone or gypsum quarry. (Passed by the Ministère de la Guerre, Paris.)

## INDUSTRIAL ALCOHOL.

Useful Notes concerning a Fuel which can be Produced in almost Unlimited Quantities.

ALL who are interested in the fuel question—and what motor cyclist is not?—should read “Industrial Alcohol,” by Robert N. Tweedy, published by the Co-operative Reference Library, Plunkett House, Dublin. This is an informative book of eighty-eight pages, dealing with the question of industrial alcohol in a most thorough and efficient manner. The reading of the treatise is extremely interesting in view of the leading article appearing in the last issue of *The Motor Cycle* on the subject of alternative fuels to petrol. This article states that “alcohol produced from potatoes is spoken of as a probable solution (of the petrol-difficulty), but obviously the product, if procurable—which, of course, it is not—would be liable to taxation.” Thus the case for alcohol is quite impracticable at the present time, even if it were produced in quantities, on account of the obstructive legislation.

### German Forethought.

The book goes on to point out that Germany saw the possibility of alcohol being used without vexatious restrictions in the arts, crafts, and sciences. In 1891 she freed industrial alcohol entirely, with the result that in 1904 the German industries consumed 73¾ million gallons of non-potable alcohol manufactured from the products of her own soil.

An interesting feature about the treatise is that the question of fuel in motor vehicles is dealt with pretty extensively. The distillation of alcohol from potatoes seems to be a great success in the land of our enemy, a vast quantity being used for lighting, heating, and cooking, while the number of agricultural and other engines built specially to use alcohol has grown very rapidly. There are now many thousands at work.

“The most striking evidence of the importance of the native supply of liquid fuel,” says the author, “is given in a paper read by Professor Vivian B. Lewis in February, 1915, in which he says that when the Russians had over-run Galicia, and shortage of petrol seemed likely to paralyse the German transport service, every motor car in the empire was adapted to run on alcohol.”

### A Suitable Mixture.

Speaking of its suitability for internal combustion engines, Mr. Tweedy demonstrates that it has many points of superiority to petrol, but it suffers from the serious defect of not sending off vapour readily enough to start an engine without the application of heat; this is, however, overcome by mixing it with benzole. When used in a petrol engine it cannot develop its full power, and that is one of the difficulties to be faced, as a long time must elapse between the introduction of alcohol for general use and the superseding

of the petrol engine by an engine designed for the use of alcohol. Petrol and alcohol do not mix, but benzole and alcohol dissolve readily in each other in any proportions, and the Germans made their petrol substitute with a mixture of which 80% was alcohol (95% strength) and 20% benzole, with a little naphthalene dissolved in the latter to give it greater heating power. This mixture, entirely home produced, gives five-sixths the power of petrol in a petrol engine.

In our opinion, at any rate, there is no reason why the same ingredients could not equally well be produced in England. The writer goes on to say, “This difficulty of starting is one which is sure to be overcome when a sufficient number of people are interested in the matter, and it is quite likely that several solutions will be disclosed after the war. For instance, acetylene is soluble in benzole and in alcohol, and that may have special value in the experimental work which will have to be carried out when opportunity permits.

### Fuel and Water.

Mr. Tweedy tells us some interesting facts concerning alcohol. Water mixes perfectly with it, and thus renders it the safest of the lighter liquid fuels. A petrol fire is difficult to extinguish because the flaming oil floats and spreads on the water which is poured over it. Flaming alcohol, however, mixes immediately with the water, and the fire is subdued directly the mixture has become diluted to such an extent that combustion cannot continue. For the same reason, a few drops of water in a carburettor in which petrol is used will cause an involuntary stop, whereas the only question with alcohol is whether higher economy is to be obtained from the engine by the addition of water.

M.G.C. (MOTORS) IN TRAINING. Roadside tyre repairs to a Vickers-Clyno machine gun outfit.

## TIME TO LIGHT LAMPS

SUMMER TIME.

Aug. 16th	...	8.50 p.m.
" 18th	...	8.47 "
" 20th	...	8.43 "
" 22nd	...	8.39 "

### Kent Coast Road Closed.

Motor cyclists should note that the popular and direct coast road from Ramsgate to Sandwich, via Pegwell Bay, is now closed to the public. The alternate road necessitates a long inland detour. On the coast road from Deal and Dover to Folkestone there are other restrictions. Motor cyclists should stop when challenged, and no camera may be carried.

### Bradbury Balance Sheet.

In submitting their statement of account for the year ended June 30th, 1917, the directors of Messrs. Bradbury and Co., Ltd., recommend the payment of a dividend of 10% on the preference shares for the half year and 5% on the ordinary shares for the year (both free of income tax). Together this will absorb £3,763 2s., and carry forward the balance of £11,237 0s. 3d.

### The United Kingdom and Canada.

It is reported that at a recent meeting of the Winnipeg Board of Trade (Chamber of Commerce) a new standing committee was appointed for promoting trade between the United Kingdom and Canada. The committee is to be known as the Imperial Trade Committee of the Winnipeg Board of Trade, and it is prepared not only to answer all questions from British manufacturers bearing on the trade within the Empire, but to receive and have displayed samples from British manufacturers. Communications should be addressed to the Secretary, Imperial Trade Committee, Winnipeg Board of Trade, Winnipeg.

### Coal Gas as Fuel.

In last week's issue of *The Light Car* there appeared an article, "The Coal Gas Bubble." This is nothing to do with Coal Tar Soap, but deals with the utility of the various efforts that are being made to use coal gas as a fuel for light cars. It is pointed out that the bulk or weight of the gas storage equipment practically debar the idea from success, and we may add that, even if some effective method of using coal gas were introduced, the authorities would probably bring in some new restriction, while it is conceivable that a bad smash with a gas car would be unpleasant.

A coal gas motor omnibus is illustrated on this page, and the size of the gas receptacle, which holds sufficient to

## SPECIAL FEATURES

DARTMOOR AS A TOURING CENTRE.  
COOLING THE ENGINE INTERNALLY. A HOME-MADE VARIABLE GEAR.

convey the vehicle only ten miles, gives some idea as to how impossible the scheme would be for a motor cycle. It would be necessary to carry the gas bag on a special sidecar chassis. Would it lift on corners?

### For Testing Purposes.

It is well known to our readers that Messrs. A. J. Stephens test all their engines on the bench by the use of coal gas. It is found that the engines run considerably better on this fuel than on petrol, and that they develop less power.

### A Stolen Motor Bicycle.

In the August 2nd issue of *The Motor Cycle* in "Current Chat" mention was made of the fact that Mr. J. E. D'Eath had had his motor bicycle stolen from him. Mr. D'Eath now informs us that a man was caught together with a friend, on the stolen motor cycle at the end of last month. During the proceedings in court it was alleged that they had given two worthless cheques in exchange for a Triumph and sidecar and a Rudge-Multi. The case, we understand, is to go to the Old Bailey and to be heard on September 4th.

### The Fascination of the Road.

Flying men say that after the thrills of novelty are worn off, flying (amidst peaceful surroundings) becomes deadly dull compared with motor cycling. There are no sudden changes of scenery or wayside incidents to enliven the spin, and a three hours' journey by plane is quite a monotonous affair.

### Universal Petrol Shortage.

Recent news from America conveys the idea that petrol scarcity is seriously to be expected out there. It is quite conceivable that ere very long American motorists will be suffering the irritation of the petrol permit.

### The Ladies' Ideal Mount.

Our paragraph on this page some weeks ago anent the most suitable machine for lady drivers has brought a variety of conflicting opinions, which seem to indicate that there is no one machine which can be set down as superlative as a lady's mount. We think that a light two-stroke, having a hand-controlled clutch, kick starter, single lever carburetter, and chain-cum-belt drive, would fill the bill as well as anything.

### SAVING PETROL.

The huge gas bag or tank fitted to the motor 'buses running between Shoreham and Brighton shows how utterly impossible is the use of coal gas on motor cycles unless in a compressed state. This quantity of gas is capable only of running the 'bus ten miles. The size of the tank required for a hundred miles run can well be imagined.

## Some B.S.A. Exclusive Features

No. 5.

B.S.A. BRAKES.

**T**WO extremely powerful brakes are fitted to the B.S.A. Motor Bicycle, the front being applied by an inverted lever on the handle-bar, and the rear by a foot pedal. Both brakes operate on special brake rims and allow the wheels to be removed without detaching any brake parts or disturbing the adjustments. The efficiency of B.S.A. Brakes and their strength and reliability, fully justify the confidence which riders of B.S.A. Motor Bicycles repose in them.

### The National Relief Funds.

At the week-end the principal relief funds stood as follow:

The National Relief Fund (distributed £5,641,622) .. ..	£6,218,699 0 0
British Red Cross Fund .. ..	7,182,889 19 11
Tobacco Fund .. ..	135,300 0 0

### The Overloaded Single.

Among the few machines on the road this August holiday, the overloaded single, with its badly aligned sidecar, was as painfully prominent as ever. Truly, the alignment of the average tank Holiday outfit is appalling!

### Petrol for Soldiers.

A letter in this issue under the above heading touches upon one of the greatest hardships of the present petrol position. It is certainly bad luck that those who have been abroad for long periods on the country's service should be unable to use their machines, which often afford the sole means of visiting their friends, when at length leave is obtained; and we would urge again that short leave permits be issued for men at home from abroad. The problem is, we admit, a knotty one, but it is not insurmountable, and the amount of petrol used in this way would be small.

### Sidecar Drivers Wanted.

There are a few vacancies for motor cyclists in the Transport Department of the Metropolitan Special Constabulary. Men with sidecar combinations are particularly required. Mr. A. C. Harnden, Director of Transport, in his letter to us, states: "When some time since you were good enough to insert a similar intimation, there was no difficulty in filling all the available posts, and I am sure that amongst your numerous readers there are many who will be willing to devote a few hours each week to the useful work, which has been carried on continuously since the outbreak of war by those who have now been called to wider and more strenuous service in His Majesty's forces. Full particulars may be obtained from Room 589, Scotland House, New Scotland Yard, London, S.W.1."

### Alcohol as Fuel.

On reading an article in this issue entitled "Industrial Alcohol," motor cyclists will learn that this possible fuel will mix readily with water—a fact which many already know. But since a given quantity of the fuel is capable of yielding only a certain number of heat units, it must not be thought that it would be possible to eke out the supply simply by adding a percentage of water.

Recently we have heard stories of motorists going to garages and deliberately pouring water into their tanks. Is alcohol the solution to the mystery?

An increased mileage could (theoretically) be obtained, however, by adding water to the alcohol—up to a certain point. In the present-day engine we have fins to dissipate the heat, but in the alcohol-water engine this heat, instead of being wasted thus, would automatically be absorbed by the water vapour, thus causing expansion. We may yet have silent-running engines with cylinders of the Thermos flask variety.

### Triumph Cycle Co., Ltd.

Shareholders of the Triumph Cycle Co., Ltd., are being called to an extraordinary meeting to be held on the 20th inst. for the purpose of passing, if thought desirable, resolutions (1) to capitalise the sum of £160,000, being part of the undivided profits of the company; (2) for the share capital to be increased to £290,000 by the creation of £160,000 new ordinary shares of £1 each. On these resolutions being confirmed at a later meeting, it will then be proposed that the sum of £130,000 now standing to the credit of the company's general reserve, and the sum of £30,000 standing to the dividend reserve, be applied as dividend at the rate of £2 per share, free of income tax, on the issued ordinary shares, and that this dividend be applied in payment in full of 160,000 ordinary shares, the shares to be credited as fully paid and distributed amongst the holders at the rate of two new ordinary shares for every one ordinary in satisfaction of the dividend.

### Origin of a Rumour.

It is possible that reports current concerning the sale of war-worn motor cycles and lorries at a certain M.T. depot are due to two auctioneers' boards erected amongst the dumps and in view from a railway and main road. On one the lettering is "For sale," and on the other board, "To be sold." A hurried glance suggests the sale refers to the motors instead of the freehold land. Both boards have been there for some time.

### AVERAGE PRICES.

WE give below the prices of second-hand machines offered for sale in the last issue of *The Motor Cycle*, and in the adjoining column the average prices based upon the latest figures available. Thus the general trend of the market is visible at a glance, though in the first column many blanks inevitably occur. This is due to an insufficient number of one model on which to base an average. The word "combination" indicates a sidecar outfit as supplied by the makers, while "sidecar" implies that the fitting has been carried out by the owner.

### MUNITIONERS UNDER CANVAS.

Many Midland munition workers spent the August recess under canvas in the woodlands of Stoneleigh Deer Park, the little Levis two-stroke proving a most useful adjunct, especially when there was shopping to be done.

## WHAT SHALL WE CHOOSE?

IT is interesting to read the pros and cons put forth by different riders in reply to the query that appeared in the editorial columns a few weeks ago anent the best machine for a lady. One rider having obtained satisfaction and pleasure from a certain type of mount will plump for the make every time, scarcely allowing that all designs have their good points and possibly a few failings. Everything depends on the type of woman; one person will feel "wobbly" on anything with a higher-powered engine than an autowheel, whilst competent drivers will handle a big single or twin with dexterity. A great deal of the confidence acquired is due to knack and skill, and it would be best for nervous women to keep to low-powered open-framed mounts.

I have ridden many makes of motor cycles, and I should be undecided which to recommend, unless I

Levis, and a Clyno. Any of these machines would have been a good investment for a beginner, or even an experienced rider.

### Two-strokes.

There are points in favour of the two-stroke machine. Some riders contend that it is the lightweight of the future, but, all things considered, I personally favour the four-stroke. The two-stroke will climb well, but not so well as the four-stroke with three speeds.

If price were no consideration I would drive a big four-stroke sidecar combination and a light two-stroke with single gear for short journeys and fairly level roads. A little single-gear machine rides with more life than one that is encumbered by the extra weight of gears. Although not such a go-anywhere mount, the two-stroke is usually cheaper owing to dispensing

Many lady riders prefer the ordinary type of frame to the open variety.

had a fair idea of the tastes and disposition of the rider. For solo work a  $2\frac{3}{4}$  h.p. engine is as useful as any, as it has sufficient speed for practically all purposes without the need for great weight in the frame and fittings. I remember, amongst others, the pleasure I derived from a lady's Douglas, a Velocette, a

Miss Rosina Higgs, a hospital nurse at Dartford, uses her Douglas for the purpose of riding from her home in Reading to her work at Dartford.

The ordeal of the interviewed.

with valves and timing gear; but the initial cost is not the only one to study. Again, it is claimed for the four-stroke that consumption of petrol is lighter. This is certainly so, but most women will find that tyres are a bigger item than fuel. A gallon of petrol will carry one such a long distance that the few pence spent in that direction are hardly felt.

## Through Feminine Goggles.--

Nowadays many women despise feminine attire, and a modification is certainly necessary for many occupations. For myself, I prefer to stick to the frequently scorned skirt, and find it no disadvantage at all when motor cycling, although I may claim to have had a fair share of experience; but I can also admire some of the neat copies of masculine attire donned by some feminine riders. I recently saw a smart outfit worn by a lady on a 3 h.p. Enfield. It consisted of khaki twill knickers, a coat to the knees of the same material, made after the "trench" coat pattern, with soft leggings and boots and crowned by a small hat made from material similar to the costume. It was most suitable for country work of any description, but one would no more care to dress thus for town shopping than a farmer would attend his church wearing a smock. To say that one requires *bizarre* apparel to ride an open-framed mount is absurd. I remember that Miss Hammett, of Douglas fame, never appeared in club runs, or in the much more strenuous reliability trials—in which, by the way, she proved no mean competitor—in any garb at which the most fastidious Mrs. Grundy could cavil. However, as prejudice regarding woman is going to "the wall" in most ways just now, we shall probably soon allow

any kind of weird fantasy in dress to pass without comment.

The majority of fair riders are using diamond-framed machines, partly owing to the fact that the menfolk of the family have entered the forces, leaving their mounts behind, and partly because the manufacturers are too busy and labour too scarce to give any attention to open-framed mounts. The lady in the illustration—Miss Higgs, a hospital nurse, of Dartford—prefers the man's frame, thinking it more rigid than the open variety. Had she been more familiar with the lady's Douglas before purchasing her present model I think she would agree with me that the lady's machine is practically perfect in design and quite fast enough for her purpose. She is able, although almost a novice, to carry out small roadside repairs, and she has never yet experienced a broken valve or any serious breakdown, which speaks well for the machine. She tells me that she considers nothing teaches one the mechanism better than to suffer inconvenience through ignorance. She is amused at the photographs one sees of roadside repairs in some periodicals, as she says the most interesting bit of work requires doing when the camera is left at home, and in moments of emergency one is apt to find that a few reliable tools are worth dozens of pictures.

## Cancellation of Petrol Licences.

**F**OLLOWING the protest made by the Automobile Association to the Board of Trade against cancellation of petrol licences issued prior to April and May last, the following correspondence has ensued between Major-Stenson Cooke, secretary of the Automobile Association, and the Deputy Petrol Controller:

### From the Deputy Controller.

8th August, 1917.

Sir,—I have to acknowledge the receipt of your letter of the 31st July addressed to the Secretary to the Board of Trade, submitting a protest, on behalf of the members of your association, against the recent notice issued by the Petrol Controller, whereby full-duty petrol licences of the first and second issue have now been cancelled.

While it is true that until recently the policy of this department was to permit the purchase of petrol against licences at any time subsequent to the date of issue, no undertaking was given that such policy would be continued indefinitely.

The petrol situation is now more critical than hitherto, and there is small prospect of any material improvement in the near future. The Controller feels compelled in these circumstances to take every possible step to limit the petrol available for civil consumption to purposes of absolute necessity. It is thought that holders of first and second issue licences, which at this late date are not exhausted, have had full opportunity of purchasing and using the restricted quantity of petrol issued against their written statement of requirements, and that, save in a very few exceptional cases, there is no consideration of necessity to justify the extension of the period of the validity of such licences.

The Parliamentary question referred to in your letter would appear to relate to stocks of petrol, which are not affected by the notice issued by the Petrol Controller.

I am, sir,

Your obedient servant,

P. G. L. WEBB, Deputy Controller.

The Secretary, The Automobile Association  
and Motor Union.

### Major Stenson Cooke's reply:

8th August, 1917.

Sir,—I have to thank you for your letter of the 8th inst., in reply to the protest submitted by the Automobile Association against the recent notice cancelling petrol licences of the first and second issue.

This association fully appreciates the importance of preventing unnecessary consumption of petrol, but in view of the fact that motorists have from the commencement of the war placed their cars, personal services, and their petrol allowances freely at the disposal of the country, I would urge they are entitled to more considerate treatment than sudden cancellation of allowances, because their licences have been sparingly exercised.

In reply to your statement that no undertaking was given permitting the purchase of petrol against licences at any time subsequent to the date of issue, I would draw your attention to the following footnote which appeared until very recently upon your forms refusing renewals of licences:

"Your present licence, which is valid until the total quantity of petrol allowed thereunder has been purchased, should be returned to this office as soon as it is exhausted."

I am to point out that many motorists, holding the assurance or "undertaking" conveyed by this footnote, decided not to avail themselves of the Chancellor of the Exchequer's concession permitting them to surrender their car licences on June 30th in return for a refund of half the amount paid in respect of motor car or motor cycle taxes for this year.

In consideration of such motorists having retained full Inland Revenue licences for this year, may it be suggested that your notice cancelling early petrol licences should be strictly confined to those held by motorists who relinquished their car and motor cycle licences on June 30th? If this suggestion be adopted much of the unmerited hardship referred to in my previous letter will be avoided.

I thank you for the assurance conveyed in the last paragraph of your letter that stocks of petrol obtained under early licences are not affected by the recent notice.

I am, sir,

Yours faithfully,

STENSON COOKE (Major), Secretary.

## THE ZENITH SPRING FRAME.

A System of Springing designed for Gradua Gear Machines.

It is at once obvious that in the case of a machine fitted with a Gradua gear, by which the back wheel is to move longitudinally in relation to the main frame, some special provision must be made for the sliding action of the wheel if rear springing is to be incorporated. In the new Zenith spring frame this provision is made without very wide departure from standard Zenith practice, and the accompanying illustrations show at a glance that the manner in which the movement of the rear wheel is effected coincides with the well-tried system employed on the rigid frame models.

In this design the back wheel forks are pivoted to the main frame, so that they can move in a vertical plane independently of the main frame. The leaf springs extend directly above these fork tubes, being mounted on the main frame at their base and shackled to the fork members at their opposite extremity adjacent to the wheel spindle. Thus, any vertical movement of the rear wheel falls directly on the springs which support the weight of the machine, the fork members acting, as it were, as radius rods.

These fork members, carrying the rear wheel, are moved backwards and forwards in much the same manner as in the ordinary rigid frame Zenith-Gradua, but the shackles to which the springs are attached at their rear extremity are so arranged that they can slide on specially faced surfaces, thereby allowing for

A patented spring frame designed by F. W. Barnes for the use of the Zenith-Gradua motor cycle.

the flexibility of the springs and for the necessary variations in the wheelbase.

It will be seen that every provision is made for the exclusion of grit from the sensitive working parts. The design is, perhaps, rather on the heavy side, but probably modifications will be made ere this spring frame model reaches its final stage.

### HELPING THE RED CROSS SOCIETY.

Several of the Coventry firms have purchased trailer ambulances, which they lend to the Coventry V.A.D. for the conveyance of wounded soldiers. Among the firms are the following: Messrs. Alfred Herbert, Ltd., Mills-Fulford, Ltd., Singer & Co., Ltd., Rudge-Whitworth, Ltd., and Coventry Ordnance. One trailer has been presented outright to the V.A.D. by the employees of the Humber Saw Mills Department, and another by the Coventry Gun Club. We hope that this good example will be followed. An inspection of these ambulance trailers by Brigadier-General Quale Jones, C.B., C.M.G., recently took place in the Charterhouse Grounds, Coventry.

## D.R.'S AND THEIR WORK.

(IN FOUR INSTALMENTS.)

### II.—VARIETY OF WORK.

By D.R.

**T**HERE are many different kinds of work allotted to D.R.'s. The work of some men seems of very little importance, but it may prevent much harm being done by enemy spies. I refer to the patrol work done by many D.R.'s.

These men are sent out night after night over certain stretches of road, generally along the sea-shore or in view of the sea, to report on any unusual lights or signalling, and to halt and enquire the business of any stranger in the district. It is very seldom, however, that the motor cyclist patrol actually sees anything to report. The mere fact being known that he is in the district will prevent enemy spies from attempting their work. He soon gets to know the roads very thoroughly, and rides without lights, and so can see without being seen. He varies the times and routes of his journeys and his watching posts at his own discretion, so that no one actually knows where he is at any particular time. For the first few nights on this patrol work, and until properly acquainted with the district, one is inclined to be very suspicious of every light in the neighbourhood. On a very dark night it is quite impossible to judge whether a light is very large and some miles away or very small and only a few hundred yards away. Any light which flickers or frequently becomes obscured immediately arouses suspicions of signalling, and one can almost imagine dots and dashes being signalled across country or out to sea, though, of course, no coherent message can be read. Such lights when investigated usually prove quite harmless, such as a bush blowing to and fro before a light in a cottage window, or a lantern being carried with a swinging motion.

#### The Dangerous Side.

I know of one D.R. who was on patrol duty for several months on the shore of a bay with a very narrow opening, completely hidden from the open sea by an island. On the map this might appear a likely place for a base for enemy submarines to replenish supplies. As a matter of fact the bay was only a few inches deep for an hour at high tide, while at low tide it was all mud and sand. Of course, there never was anything to report, nor was there likely to be, as submarines could not possibly get within miles of the place, nor could any signalling be carried on between there and the open sea.

I have seen a D.R. tearing twenty or thirty kilometres across country and arriving at his destination with such importance that one would imagine that the whole fate of the British Empire depended on the prompt delivery of his despatch. As a matter of fact,

the actual message was a request for a quartermaster-sergeant to exchange a tunic for an orderly room clerk!

But, putting aside the farcical side of a D.R.'s work, there are many D.R.'s who really do good work and carry important messages. Some of them are frequently or almost continually exposed to danger. The casualties from enemy fire among D.R.'s are, however, very few. Enemy machine guns have been trained on portions of exposed roads covered by D.R.'s, and under such circumstances the D.R. is lucky to get past without a single bullet striking him or his machine. Other parts covered by D.R.'s are exposed to shell-fire, but the cute D.R. can sometimes from a comparatively safe place estimate the time between each shell coming over and take advantage of an interval for a dash through the danger zone. I frankly admit I know very little of this dangerous side of a D.R.'s work, as I have never had to go into any actual danger as a D.R. myself. I do, however, hear very thrilling experiences from other D.R.'s who are frequently exposed to danger.

#### Roads.

Yes, D.R.'s have to cover roads and roads (?). In some parts we find only roads (?), and it is very hard lines on the D.R. whose work keeps him entirely on them, but he is probably the man who sticks to his job and makes little or no complaint. There are ruts, pot-holes, mud, and greasy *paré*, and I know what these are like during a thaw after a long spell of hard frost and snow, or with a three-inch covering of snow melting in a few hours. I also know what these same roads are like on a dry windy day when there has been no rain for a week or so. They have already been photographed and described so often that it would be useless for me to try to depict the conditions. But one seldom sees photographs or hears of the very fine, straight stretches of perfectly smooth, level, road regularly covered by some D.R.'s. Though I am inclined to agree that many riders like to enlarge upon the difficulties, I cannot say I have actually seen a road specially prepared with mud and boulders ready for the photographer so as to exaggerate in the press the difficulties of the D.R.'s work, but I have seen D.R.'s taking quite unnecessary rides over the very roughest tracks and having their photographs taken in places where they never have any actual duty.

(To be continued.)

#### GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD.

# GREAT AMERICAN RECORDS BEATEN.

"Cannonball" Baker's Remarkable Speed Record Eclipsed.

**L**ESLIE PARKHURST, astride a 1917 Harley-Davidson, officially checked and scored by the Federation of American Motor Cyclists, covered 1,452 $\frac{3}{4}$  miles between 7 p.m. July 19th and 7 p.m. July 20th on the two-mile board speedway at Sheepshead Bay, N.Y. Parkhurst's feat eclipses the present twenty-four hour solo record—made three weeks previously by E. G. Baker on an Indian at the Cincinnati Speedway—by 66 $\frac{1}{2}$  miles.

Parkhurst also made new records for the 500 miles and 1,000 miles, riding the former in 7h. 35m. 17s. and the latter in 17h. 8m. 28s. Baker's record figures for the distance, also made on the Cincinnati Speedway, were 8h. 38m. 30s. and 17h. 26m. 30s. respectively.

Parkhurst lost 3h. 45m. due to rain, tyre, and fuel stops. His average speed, based on actual riding time of 20h. 15m., was 71.24 miles an hour.

Otto Walker, with Carl Lutgens as sidecar passenger on a Harley-Davidson-Rogers sidecar combination, and riding the track simultaneously with Parkhurst, succeeded in adding 158 $\frac{3}{4}$  miles to the twenty-four hour sidecar record made by C. F. Bruschi—also on a Harley-Davidson—a month ago at El Centro, Cal. Bruschi rode an even 1,000 miles in the interval, while Walker piled up a mileage of 1,158 $\frac{3}{4}$ . Walker made nine stops, aggregating 1h. 24m., so that his actual running time was 22h. 36m., and his average speed, based on this figure, 47.02 miles an hour.

Leslie Parkhurst, third from left in sweater, stops for adjustments during his ride of 1,452 miles in twenty-four hours.

Otto Walker and Carl Lutgens, who succeeded in adding 158 miles to the twenty-four hours American sidecar record.

## PETROL FOR AMERICA.

A Critical Position: The Question of Demand and Supply.

**T**HAT the petrol situation in America bids fair to approximate conditions now prevailing in Europe can be gathered from the fact that Senatorial conferences, now working on the Government's food and fuel conservation, intend to place petrol, paraffin, and other fuel oils under Government control as a means of preventing wastage.

Following closely on the heels of this announcement comes a warning from A. C. Bedford, president of the Standard Oil Co., to the effect that if we are to be ensured a sufficient supply of the hydro-carbon fuel to win the war, motoring activities along pleasure lines must be curtailed, if not stopped altogether.

Mr. Bedford said: "If our Government is to have the petroleum it will need to prosecute the war successfully and supply all necessities directly growing out of the war, two steps will have to be taken, viz.:

"(1.) The public will have to economise in the use of petrol. Sufficient petrol should be available to provide for all the normal uses of automobiles. But pleasure riding should be curtailed. People should look upon their automobiles as necessities to be used

only when needed. Not a gallon of petrol should be used except for some useful end.

"(2.) Every oil-producer in the country should be encouraged as a patriotic effort to secure the utmost possible output of crude oil."

Against the pessimistic view of the situation taken by Bedford comes the statement from Henry L. Doherty, president of the Cities Service Co., and second largest producer of refined oil in America, to the effect that if the public adopts Bedford's suggestion for relieving the situation the curtailment of pleasure motoring will speed the petrol famine.

In substantiating his statement Doherty brought out the fact that the cost of drilling oil wells is almost prohibitive at the present time, and with the Government willing only to pay two cents a gallon for fuel oil, the oil men depend for revenue on the operators of motor vehicles, who are willing to pay up to thirty cents a gallon for petrol. With the profitable end of their business cut off, according to Doherty, all incentive for the oil producers to drill more wells and increase the supply will be stopped.

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

### ACTION AND REACTION ARE EQUAL AND OPPOSITE.

Sir,—I should like to ask "Mohandis" the following question: If, as he says in *The Motor Cycle*, page 135, "the engine causes the tyre to exert a backward force on the road surface" and "the road exerts an *equal* and opposite reaction on the tyre," what pushes the machine forward? Surely an *equal* "reaction" would merely cancel the "action," and an equilibrium result? T. RAE.

### WHY NOT ACETYLENE?

Sir,—Why cannot we get at the bottom of the difficulty in the use of acetylene gas in petrol engines? Let some of our qualified scientists give their opinion and advice, and let us see what can be done. One might even offer a prize for the first successful trial of acetylene gas on a motor cycle. Hundreds of motor cyclists would willingly subscribe money towards a prize, and the war has made us master worse difficulties than this. Let the motor cyclist master his own problems. It would be a lasting boon. Liverpool. McADAM.

### TWO-STROKE PISTON RINGS.

Sir,—I am interested in the correspondence on the benefit of Oildag on piston rings, but I should like to know whether its use has any disadvantages.

I have used it for a short time in a  $3\frac{1}{2}$  h.p. four-stroke engine, and found the rings in a much better condition than usual. But I also found metallic flakes inside the piston, evidently caused by the Oildag being burned or melted.

Now I should like to know if there is any danger of the flakes falling into the crank case and doing damage. Canterbury. I.W.G.

### INVERTED CONTROL LEVERS.

Sir,—My attempt to raise the question of the anatomical aspect of inverted control levers has elicited criticism from three gentlemen, none of whom has succeeded in refuting the opinion I expressed in my original letter—namely, "that the entire contour of the normal type Bowden lever gives the complex muscle system of the hand a correctly-graduated load."

My own driving system involves regular use of both valve lifter and front brake levers—the former for coasting downhill with the throttle shut, the latter for all minor decelerations if the machine is travelling in a straight line. In a hundred miles run, therefore, as I have made considerable use of both levers, I appreciate the type which requires the minimum effort. Someone might try the experiment of fitting his handle-bar clutch control to an inverted type lever, use it for a month, and publish his results.

In reply to his criticism, perhaps "A.H.F." will substitute "onns of operation" for "hard work," and realise that I used the term "hard work" to differentiate between the varying degrees of leverage provided by the different portions of any lever. In reply to the Rev. R. C. Measures's questions I may say:

(1.) I have already explained that I use both levers to a considerable extent.

(2.) I find that for any given operation the normal type requires less effort.

(3.) Delicacy of control applies principally to the front brake lever. With the normal type lever the requisite pressure for a gradual deceleration can be more easily and "delicately" applied. Locking of the front wheel, always an unpleasant happening, is thereby avoided.

The Rev. R. C. Measures implies that what the manufacturer gives us is, *ipso facto*, correct. Perhaps the percentage of inverted type front brake levers, as fitted to a certain machine here, that remain operative after a short period of active service would surprise him, but I leave that side of the question in the abler hands of "Chinook." A. LINDSAY, CAPT., R.A.M.C. B.E.F.

### AVERAGE SPEED.

Sir,—I am inclined to agree that a high average speed, covering a long distance, requires an extraordinary mount and extraordinary luck as regards conditions. A run of 106 miles, non-stop, from London to Bournemouth I once accomplished in 2h. 45m. on a not-too-much-faked  $3\frac{1}{2}$  h.p. N.S.U. (before the war!); this is an average of 38.5 m.p.h., and meant a speed of over 50 m.p.h. whenever I got the chance. On trying London-Torquay (about 212 miles), my time rose to 7h. 10m., not including a stoppage to refill, making the average speed fall to 29.5 m.p.h.

The 'bus in question was well known in a certain part of London as being faster than the average single. I have never beaten the time for the former run on 5 h.p. and 6 h.p. machines that I have since possessed, though the latter, a 6 h.p. Bat-Jap, is faster than the N.S.U. when it comes to a "dust-up." I find there is always something that goes wrong with the twin when driven at these speeds, though the engine is not taxed so much.

B.E.F.

USCANOPIT, R.F.C.

Sir,—"Armidug," in your issue of July 26th, claims to have motor cycled from Arnèke to Saint Omer at the average speed of 47.85 m.p.h. He states the distance to be twenty-three and threequarter miles; this makes his time to be nearly thirty minutes. But the actual distance between these two towns, by main road through Cassel and Arques, is only sixteen miles; so his average speed amounts to about 32 m.p.h., which is what one might reasonably expect. There are at least two other feasible routes which he might have taken, the lengths of which are fourteen miles and ten and a half miles respectively.

(PTE.) J. C. BENNETT MITCHELL, M.M.G.S.

B.E.F.

Sir,—We read in your issue of July 26th, with an amount of interest, of "Armidug's" performances on a  $2\frac{3}{4}$  h.p. war model Douglas, and we were surprised.

In the first place, Arnèke is only a matter of ten miles from Saint Omer, and, even if a circuitous route were taken to strike the main Cassel road, the distance is only about twenty-three kilometres! We suggest that "Armidug's" calculations became somewhat mixed. The "stop watch" used must have stopped for quite a considerable time.

Supposing, however, the distance to be correct, an average speed of 47 m.p.h. is rather a tall order for a machine that can only do 52 m.p.h. in a "flying kilo," and we have yet to find the "war model Douglas" that, with only "a tuning up," can do much over 40 m.p.h., even if the roads here would allow of it, and even at this speed the engines soon overheat with the petrol and oil as supplied on active service. THE SCRUFFS, D.R.'s, R.E.

P.S.—"The Scruffs" include one D.R. who has a much stronger claim to being "the youngest D.R." than Cpl. Roughley, whose photograph appeared in the issue of July 26th, he being only 17 years 1 month on his arrival in France sixteen months ago.

### PETROL FOR SOLDIERS.

Sir,—I am writing to ask if you think there is any possibility, supposing I am able to get home on leave, of obtaining any petrol for my motor cycle. I left England in August, 1915, and so when I get home—if I do at all—I shall have been well over two years continuously on active service without a single day's leave.

Under the circumstances I think it pretty hard luck if I am not allowed a few gallons for use during the fortnight or so I am at home, especially living, as I do, well away in the country, for with a restricted train service a motor is the only means of seeing the people one wishes to see. As a matter of fact, I had only about four months use of my Inland Revenue licence in 1915, as I renewed it about April and did not use the motor cycle after the end of July.

Your paper is one of the joys of life. I have had it posted every week since I left home, and have lost few copies.

KENNETH DAWSON (Capt.)

### COOLING THE ELECTRODE.

Sir,—In *The Motor Cycle* of May 10th "The Critics" continue their most interesting discussion about plugs, and, in view of what the four gentlemen say, I would like to suggest making the central electrode of sparking plugs hollow, with a double bend at the top open to the air, the bottom being pointed and closed, the idea being that one opening being pointed to the direction of travel, the rush of air would always keep the electrode comparatively cool. I am not an engineer or a mechanic, but the idea may be feasible.

GEO. J. HIDE.

Buenos Ayres,  
Argentine Republic.

Cooling the central electrode  
by air circulation.

### THE CRITICS.

Sir,—I like "The Critics" as much as anything in your paper. I often wonder if these are genuine conversations. They surely must be, because "D.R." exhibits all the limited intellect which I have frequently observed amongst D.R.'s, and "Manufacturer" is absolutely typical of the half-educated, pigheaded, purblind tinker who sets up to design motor cycles for the greatest Empire in the world.

In a recent issue "Manufacturer" unloaded a lot of heavy sarcasm on riders who ventured to interfere with the silencing arrangements as provided by the maker. The silky silence of a Harley or a Henderson is a joy to me, but I discard the silencers of most British productions simply out of self-defence, because I cannot stand the filthy jangle of the timing gear. "Manufacturer" calls this swank, though, personally, I can see nothing very swanky in making a hideous din. As the revolutions of the average British engine are usually grievously disproportionate to the speed, a noisy exhaust merely gives the show away. "Manufacturer" excuses his beastly timing gear by a little hot air about the superiority in volumetric efficiency of the British engine. What in the world has volumetric efficiency to do with the private owner? May the powers defend me from any more volumetric efficiency! Just when you want it, it is not there. As a matter of fact, it never is there except for the first half-mile after starting from cold.

I assert with deep regret that at the present moment our manufacturers are years and years behind the Americans in the quality and performance of the machines they are turning out. Some ten years ago the British industry had an absolute lead, due, in my opinion, to two things, namely—(a) the Triumph Cycle Co., and (b) the natural aptitude of the British public for this form of locomotion. All honour to the Triumph Cycle Co. They made motor cycling possible, and have produced a type of motor cycle which, though personally I consider it an undesirable type, is nevertheless an engineering job from stem to stern. But what of the others? (1.) The pitiful two-stroke. (2.) The feeble and remote copy of the Triumph. (3.)

The awful pile of wires and sprockets, rods, knobs, spikes, and angles hung promiscuously round a ponderous framework, and sold at a price in excess of the Ford car.

I could go at length into the points of superiority of the Yankee machine only I am getting fed up with writing. It is sufficient to say it is superior on all points, and if anybody likes to argue about it I can supply some pages of facts and figures from my personal experience to support it.

Now, I do hope the British industry will get a move on. It has got another year at least before the struggle begins, and I venture to present the following suggestions absolutely gratis: (1.) It is worth paying a properly trained engineer in the designing department. (2.) Decide whether the machine is to be for solo or sidecar use, and scrap the dual purpose idea. (3.) The price must come down. (4.) The weight must come down. (5.) The "volumetric efficiency" (ugh!) must come down, and the power required must be supplied by c.c. sufficient to do it.

London, S.W.

HOWITZER, R.G.A.

[We do not share our correspondent's conviction. It would be very simple to ignore volumetric efficiency and accept the obvious alternative of piling up the c.c., but this would tend to deaden progress.—Ed.]

### EXHAUST GASES.

Sir,—I often wonder why motor manufacturers, in their intense keenness to get the utmost power and speed out of their engines, still, after nearly forty years of motor building, lead the exhaust pipes downwards and make the exhaust gases travel a zigzag course before entering the silencer. Hot exhaust gases have a natural tendency to rise, apart from the fact that they get kicked upwards violently by the ascending piston, and a certain amount of back pressure must be caused by making these gases do an "about-turn" when they come to the top of the cylinder, and are forced down the exhaust pipe. I should think it would not be a difficult matter to keep the exhaust pipe level with, or in some engines higher than, the top of the cylinder. The silencer might be fastened to the stays of the carrier. The exhaust pipe would be nearer the tank certainly, but I think if it were bound round with asbestos there would be little danger of fire.

B.E.F.

W.G.C.

### DOUBLE-ACTING FOUR-STROKE ENGINES.

A suggestion in the construction of a  
double-acting four-stroke.

Sir,—In reference to the double-acting engine illustrated recently in *The Motor Cycle*, I think that the machine work and erection could be very much simplified if the system as per enclosed sketch were adopted. It is used very much on compound single-acting straight line air compressors.

In the sketch I have merely shown the outline of the cylinder and piston without any valve pockets.

GEO. B. HALLAM.

### SIDECAR V. RUNABOUT.

Sir,—Regarding your correspondent "More Comfort's" letter in your issue of the 2nd, I should like to add that my experience is very similar to his. Before the war I obtained a great deal of pleasure from a  $4\frac{1}{2}$  h.p. combination, but have since been asking myself the question, is the modern combination worth while at its price? I have come to the conclusion that it is not, and my post-war machine will be a Morgan, Scott, or cycle car.

I am rather afraid manufacturers had better revise their ideas concerning the combination. The war will see its days numbered.

J.L.

## TWO OR FOUR-STROKE ENGINES.

Sir,—I have been very interested in your series of articles entitled "The Critics" ever since its inception, and I feel I must say a few words of praise on behalf of the light 2½ h.p. four-stroke.

My own mount is as fast as I could wish; and as for hill-climbing, it has successfully negotiated the Old Wyche, Malvern, with its gradient of 1 in 2.9. I think it in all ways superior to the light two-stroke of the same power. Its petrol consumption is low, and it will keep up a high average rate of speed for many miles without overheating.

I have touched 50 m.p.h. on my machine, and this without any freak tuning, etc., or anything beyond the attention of an enthusiastic owner. I add the usual disclaimer.

Berkhamsted.

CALTHORPE-J.A.P.

Sir,—Being a keen motor cyclist and reader of your paper for the last ten years, I feel it is only right that you should have my opinion of two-strokes, as they are only too often scoffed at. My machine is a standard model Connaught, purchased last October, since when I have been doing constant riding to and from the different camps in my district. The total mileage run is now 3,500, the belt has been shortened once only, and the back tyre is apparently good for another 3,500. From start to finish I have averaged 160 miles per gallon with a 26 jet, can touch 45 m.p.h. on a good road, and cut a figure of 8 on any main road without four-stroking, so you can judge that the engine is flexible. I might mention that I have fitted Terry's spring links to the front forks, and find them a great success on present day roads. But the thing is the Clair silencer; this was fitted without any difficulty underneath the crank case, which I find a good position, as it has a tendency to warm the gases before they are transmitted to the cylinder, but the quietness is sometimes dangerous in country lanes. This I can say, the hiss from the carburetter is now louder than the exhaust. To ride such a machine with its gentle pulling motion upon opening the throttle is far better than a four-stroke, with its "snack, snack, snack." However, every rider has his particular fancy, but give me a Connaught, and I am happy.

I wish the makers of this machine and your good selves every success, as it is owing to your paper and the makers of such machines that we are able to have a little relaxation in these strenuous times.

F. ENGLISH.

## AN EARLY COUNTERSHAFT GEAR.

Sir,—I am enclosing a photograph. As you see, it is an old machine, built in 1903. It has, of course, accumulator ignition. The chief interest, however, lies in the countershaft and handlebar-controlled clutch. This was the only

Handlebar-controlled clutch in 1903.

Bowden control on it. Front brake, exhaust lifter, throttle, and ignition, all were controlled by rods and levers. Note the band brake on the front wheel, also the long induction pipe and detachable cylinder head. The machine used to go, too, and several times made the journey from Buxton to Sheffield. I may add that up till recently the machine was running about Sheffield, and I got much fun out of it.

By the way, "Ixion" is an authority on plugs for flat twins. Has he ever tried (a) the Jap plug, sold at 2s. 6d.; (b) the Oleo car type, No. 7, 4s. 6d.? The latter has a big brass body, keeps cool, and looks nice if polished. I have found it splendid.

G. F. JONES.

## A COMMONSENSE CARRIER PLATFORM.

Sir,—All riders know how difficult it is to fasten parcels of perhaps varied shapes on to their carriers and find them safely there at the end of a journey. With the platform I suggest absolute safety is secured, and parcels are strapped or tied on almost instantaneously. The platform or grid is made of strong iron round the outside, and a stout wire mesh across—strong enough to stand the necessary pulling up of straps. The mesh is 1½ in. or 1¼ in. square, and, with a strap 1 in. wide interlaced, no moving or shaking off during the longest journey can be possible; and parcels can be fastened in the centre as easily as a parcel occupying the whole of the platform.

It may be possible to adapt this idea to many of the motor vehicles used for luggage, as the mesh could be made for straps or ropes, and of a strength necessary for the luggage. It would, I think, too, be an improvement on some of the motor car platforms, on which one sees passengers' luggage strapped or tied in very ungainly looking positions.

S. T. CHESHIRE.

## CARBURETTERS.

Sir,—Having noticed from time to time in your paper references to different makes of carburetters, I should like to state mine for the benefit of others. I have a Levis 2½ h.p. two-stroke lightweight motor cycle, fitted with Enfield two-speed gear and all-chain drive; this machine I found splendid in every detail except the carburetter, which would not allow the machine to start easily or run slowly without four-stroking. I tried several other well-known single jet makes with no better results, and finally ordered a three-jet Binks. This instrument was delivered in four days and fitted the machine perfectly—in fact, I had it on within five minutes of opening the parcel. In half-an-hour I had mastered the instrument, and the transformation it has made to the Levis is marvellous: it two-strokes perfectly at slow speeds, and I am now able to use my free engine and clutch in traffic without the engine racing. The machine will attain a speed of forty miles an hour and uses less petrol.

My lighting is electric by means of A. H. Hunt's dry batteries and lamps, and gives every satisfaction.

C. RUSSELL (LIEUT., R.E.)

## MOTOR CYCLE DESIGN.

Sir,—It has occurred to us that a few notes on the general design of motor cycles, from the rider's point of view, might be welcome, now that manufacturers' thoughts are turning to post-war models.

Here we have dealt only with what we consider to be faults in design and construction, though doubtless some of these are matters of personal opinion.

One great fault of many motor cycles is their general inaccessibility, especially in reference to the power and transmission units. This we consider deserving of more attention than it has so far received.

The next point is the need for better springing and larger tyres. Fully 50% of the motor cyclist's troubles have as origin the effects of excessive shock and vibration.

With the increase in weight and power of sidecar outfits the need for better brakes becomes imperative. Front brakes on solo motor cycles are dangerous, and on heavy combinations are almost useless. Rear brakes should be in duplicate, preferably of the external contracting and internal expanding type. Rear brakes of the type adopted from ordinary cycle practice are usually unsatisfactory for checking heavy outfits.

Brake controls, in our opinion, need attention. Foot brake controls, which have bends to avoid belt, gear box, etc., or which dive underneath the power unit and reappear on the other side, are to be condemned. Designers should remember that intricate controls look exceedingly nice in the showroom, but are apt to cause trouble after a month or so of winter running.

Again, silencers might receive more attention than they do. Two-strokes and lightweights generally seem to be ill provided for in this respect.

Composite motor cycles seem to suffer from defects in design more than those which are practically built throughout in the same factory. Probably this is largely a matter of cheapness. But there is, and always will be, a market for seemingly expensive, well designed motor cycles.

Sidcup.

F.J.W. AND F.G.

# A HOME-MADE VARIABLE GEAR.

A FRICTION DRIVE OF UNUSUAL DESIGN.

A home-made friction gear which operates entirely the reverse from usual practice.

The gear with outer disc removed, showing countershaft with sliding friction wheel.

**T**HE variable gear to be described has been fitted to an antiquated tricycle by a reader who claims that the largest tool he possesses is a carpenter's brace. The gear is unusual, and though naturally so primitive an arrangement is open to criticism, we certainly think that the inventor and maker deserves to be commended for carrying his idea into practice.

The working of the gear is as follows. On an extension of the engine shaft are two floating discs, both of which are free to revolve on the shaft. The inner disc carries the pulley or sprocket which conveys the drive to the rear wheel, while the outer disc is merely for the purpose of applying pressure to the friction wheel. This friction wheel lies between the two discs, and is mounted on a square countershaft placed at right angles to the engine shaft, but whereas in an ordinary friction drive the engine shaft disc drives the friction wheel, in this gear the state of affairs is exactly reversed.

The small countershaft wheel, driven by the engine shaft through bevels, is running always at engine speed, and, since it engages with the driving

disc, which latter is free on the engine shaft, it imparts the drive thereto—a high gear being obtained when the countershaft wheel is engaging near the centre of the large driving disc, and a lower gear as it is moved outward towards the rim of the large disc.

The outside disc, as already explained, is merely for the purpose of obtaining even pressure, thereby relieving the engine shaft and the countershaft of all side strains. The discs revolve in opposite directions, and it will be observed that on the opposite side to the countershaft is mounted a free roller to equalise the pressure on both sides of the discs. In the inside of the driving disc, between it and the engine, is placed a ball thrust, and pressure is maintained by tightly drawing up the outer disc till the small load wheel is firmly held between the two discs. The gear was made by J. F. Farris, now in France, provisional patent No. 7,965, 1917. It is operated by means of pedals, and the ratios obtainable are between 6—1 and 24—1. The pressure of the disc is instantly variable by pedal control, and a free engine can be obtained by entirely releasing the pressure.

## A Hint to Novices.

**A** TYRO recently asked me to investigate the cause of his troubles with a new machine. The first tests showed that the indubitable cause was petrol starvation. The engine started badly, would not accept extra air, ran fairly well without load on the stand or free, but could hardly be coaxed to fire at all on the road. The owner had acquired just sufficient knowledge to suspect his petrol supply, and had already proved that the feed pipe was clear, the float working properly, the carburetter slides in action, and the jet unobstructed. The explanation is very simple. The carburetter was an Amac, and, as most

readers will be aware, this vaporiser has a penthouse or metal angle plate over the jet, in which there are a number of holes, through which the petrol is sucked after it has left the jet, and so undergoes an additional mechanical vaporisation. A huge piece of fluff was tightly jammed in and across most of the penthouse holes, so that very little gas could reach the mixing chamber where the air stream joins the petrol stream. It must, of course, be a rare occurrence for enough of these holes to spoil the mixture to get blocked at the same time; but novice owners should bear the point in mind.

ROAD RIDER.

# QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of the envelope, and should be kept distinct from questions bearing on technical subjects.

## Driving a Two-stroke.

**Q.** (1.) I have a 2½ h.p. two-speed two-stroke motor cycle. When ascending hills, is it correct to change from low to top gear without raising the compression lever? (2.) Does it injure the engine to carry a passenger on the carrier?—D.E.H.

(1.) When changing up, that is from a low to a high gear, the decompressor should be operated. When changing down it is unnecessary to do so unless the gears are found to stick under load. (2.) If the carrier is strong enough to bear the weight of a passenger, and the engine is powerful enough to climb hills with a passenger on the carrier, then there is no harm in using the machine for this purpose, but the average two-stroke is a lightweight machine intended only for solo riding.

## Engine Starved.

**Q.** I have a 5.6 h.p. Peugeot motor cycle, and could you please advise me on the following? (1.) It will not take much air through the carburetter, which is a B. and B. (2.) When going on the road it will not throttle down slowly enough, and is dangerous in traffic. As regards No. 1 question, I have bound round the induction joints with asbestos and insulation tape, so cannot see where there are any air leaks.—R.S.

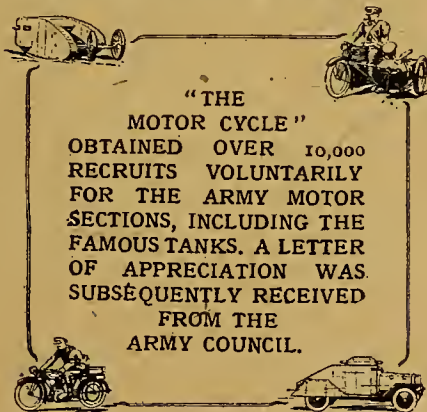

(1.) Your trouble is due either to too small a jet or to air leaks by the carburetter pistons, or valve guides. (2.) You cannot get the engine to run really slowly with automatic inlet valves unless the valve springs are too weak for efficient running at speed.

## Lack of Power.

**Q.** I have a 2½ h.p. 1912 Calthorpe Junior Precision engine. The valves have just been ground and there is good compression. It starts easily in low gear, but when put into high gear the engine stops if on the least gradient. (1.) The petrol, instead of all going into the engine, seems to blow back through the air inlet. What is the cause of this? (2.) How should this machine be timed? I cannot retard or advance spark when once fixed. (3.) There seems to be a general lack of power, yet the compression is good. (4.) I have a No. 33 jet and B. and B. carburetter. Is this too big? (5.) When I open the throttle

the engine seems to choke, and I can give it plenty of air. Is there enough petrol getting in?—G.T.

(1.) The trouble is probably due to too weak an inlet valve spring. (2.) We should recommend you to time the engine in the following manner: Place the piston 7 mm. below the top of the compression stroke, and connect up the magneto with the points just about to break. The valves should be timed as follows: Set the exhaust valve to close just after the completion of the exhaust stroke. It will then commence to open when the piston is about one-seventh of the length of the stroke from the bottom of the firing stroke. The inlet should commence to open as the exhaust closes, and remain open for one complete stroke of the piston, or while the flywheels turn through 180°. (3.) If you fit a stronger valve spring the power should improve. (4.) The jet is too large; try No. 29. (5.) The jet being too large, causes the engine to behave in the manner described.

"THE  
MOTOR CYCLE"  
OBTAINED OVER 10,000  
RECRUITS VOLUNTARILY  
FOR THE ARMY MOTOR  
SECTIONS, INCLUDING THE  
FAMOUS TANKS. A LETTER  
OF APPRECIATION WAS  
SUBSEQUENTLY RECEIVED  
FROM THE  
ARMY COUNCIL.

## A Two-stroke Defect.

**Q.** In May, 1916, I purchased a 1916 model two-speed free engine two-stroke, advertised in your columns. I did not see the machine before purchase, but a friend assured me it was all in order. During the summer and autumn its behaviour was uniformly unsatisfactory. It was in continual need of minor repairs and adjustments; neither the local garage people nor my friends could tune it satisfactorily. Towards the end of the year I broke the gudgeon pin, and left the cycle at a garage in Carnforth for repair. The people there informed me that the cylinder was scored, and would need

rebores. This they got done for me and the necessary new piston, and returned the cycle to me early this year. I was surprised and delighted with the difference, and should hardly have believed it was the same machine. Through the spring it served me well on short business journeys and to and from my work. At the end of April I made a long run, and all went well till I was nearly home, when it began to lose power and blow back through the carburetter (Senspray carburetter, Dixie magneto). Examination showed that all the holding-down bolts were slack, and also the carburetter bolt. I remade the carburetter joints and stopped the blowing back, but did not cure the loss of power. I have carefully remade the cylinder crank case joint twice, trying first brown paper and seccotine, then brown paper and oil, and believe it is tight. I have ground in the release valve and remade the joint between it and the cylinder. I have cleaned cylinder and piston top; the rings are free, so I did not remove them. Still no power. I then took the cycle to the garage at Carnforth, where I had already been served so successfully. The people cleaned the magneto points and put in a new plug, which effected a slight improvement. They admitted that the running was faulty, but they could not trace the cause—timing correct, spark good, carburetter in order, cylinder joints tight, draining plug to crank case tight. I am running on No. 2 petrol and Vacuum A oil. Last year I got 80 m.p.g., now about half that. The engine starts easily, compression is satisfactory but no power, four-strokes at slow and medium throttle openings, and occasionally misses fire; the drive is snatchy, but occasionally it two-strokes for a short burst with apparently plenty of power.—J.H.C.

Are you sure the piston has been replaced right way round? The wide sweep should be towards the exhaust port. Test the crank case joints and all other joints by running the machine on the stand and dripping oil on the suspected joints, noting if it is drawn in or blown aside. Having assured yourself that there is no leakage anywhere, test the carburetter slides for wear and slackness. If these are badly worn the strength of the mixture will vary constantly, and you will never obtain proper running. Fit new piston rings, and if these tests fail the trouble is probably in the magneto.

### Difficulty in Starting.

**?** I have a 1914 6 h.p. twin, and I have always had the greatest difficulty in starting with the kick starter, even when the machine was quite new. I have frequently kicked twenty times before the engine has fired. I have fitted two new Lodge plugs, and also had the engine cleaned. I have fitted new wires from the magneto to the plugs, and the magneto gives a splendid spark. I generally inject into both cylinders, but that does not make any difference. The most singular part about it is that if I run the machine off it will start up in the distance of three or four yards, but, of course, it is not always convenient to do that. I should be greatly obliged if you would give me your opinion on this.—G.S.

The difficulty about which you complain is not easy to solve. It looks very much as if three or four of the first teeth on the quadrant of the kick starter, which engages with the ratchet-wheel, have been broken off, with the result that you are not obtaining the full range of movement on the kick starter. Are you sure that no air leaks past the carburetter and induction pipe unions? These might well cause the trouble of which you are complaining. Again, flooding and injecting may cause too rich a mixture, and it is generally advisable to try starting up on a very small throttle opening.

### Hot Crank Case.

**?** I have a  $3\frac{1}{2}$  h.p. Sunbeam combination, and there are one or two things about the machine upon which I would like your advice. After a run of thirty or forty miles the crank case appears to be rather warm. I would not say it was hot, as sometimes I can keep my hand on it, but still I am of opinion it should not be quite so warm. The cylinder appears right in this respect: there does not seem to be overheating here. I use a 32 jet with Amac carburetter, and my usual speed is nineteen to twenty-two miles an hour. The engine and crank case have been cleaned lately, and I always, if anything, overoil. The compression is good so far as standing on the kick starter as a test goes. The heating of the crank case did not appear to take place in the winter time, but my runs then were comparatively short. What is the best method of taking off the piston rings? Would a little graphite behind the rings be helpful in preventing probable sticking? Should the rings be taken off and the grooves cleaned every time the engine is cleaned? This was not done the last time, but they were quite "free."—G.P.

We do not think that there is anything seriously wrong with your machine merely because the crank case gets warm. This it would do through conduction. An exceedingly hot crank case would mean that gas was working its way past the piston rings. Possibly during this warm weather you could use a smaller jet, when there would be less risk of overheating and better petrol

consumption. When the piston rings become badly carbonised they stick in the piston grooves, and are exceedingly difficult to remove. Many of the accessory dealers sell a special tool for expanding the rings, the points of which you can insert between the slots and gradually force them apart. A little graphite behind the rings might help matters, but when the rings stick it is nearly always a sign that the engine has been overheated or underoiled at some time. No, do not touch the piston rings unless they are actually stuck in their grooves.

### Pre-ignition.

**?** Being a regular reader of your valuable journal, I am writing for your advice concerning my motor cycle. The engine in question is a  $3\frac{1}{2}$  h.p. single with detachable valve pockets, and the trouble overheating. Everything is in order as far as I know. I have had the engine down, cleaned all carbon away from piston head and inside cylinder, made new exhaust pipe and silencer, reduced petrol jet so that when air and throttle levers are opened together it seems to be the right mixture. I have had valves correctly set, and magneto set to spark 6 mm. from top of compression stroke when lever is fully retarded.—J.S.

Your magneto is too far advanced, probably causing pre-ignition. With lever fully advanced, the points should be just breaking with the piston 9 mm. from top of compression stroke. There are many causes of overheating, which may be briefly tabulated as follow: (1.) Unsuitable or insufficient lubrication. (2.) Too weak or too heavy a mixture owing to wrong size of jet. (3.) Bad driving; running with insufficient air, or ignition too far retarded. (4.) Bad cylinder design; insufficient radiating surface. (5.) Pitted valves, slack piston rings, warped cylinder. (6.) Leakage somewhere in the combustion head.

### Indian Tips.

**?** Will you be kind enough to answer the following questions? (1.) To remove the front wheel of my 1915 road racer 7-9 h.p. Indian, do I simply have to withdraw the spindle from the hub? (2.) Can I purchase a really reliable two or three-speed gear that can be adapted to this machine without structural alteration to the frame, etc.? If so, please give the maker's name. (3.) Does the oil level on this motor cycle regulate itself and overflow excess? No matter how much I pump in on a run it is always at correct level at completion of run. (4.) What was the petrol allowance and distance run in the last T.T. race held for heavyweights? Also state average speed of winners. (5.) Is 70 m.p.g. good or just normal for this horse-power (7-9), running at an average of  $32\frac{1}{2}$  m.p.h. over a 120 mile run?—F.R.H.

(1.) All you have to do is to undo the nuts and withdraw the spindle from the hub. (2.) We do not know of any gear which can be readily fitted to this machine without structural alterations. Gears are very difficult to procure at the present time, and it is hard to find any-

one who would undertake to fit one. (3.) The oil level does not regulate itself. There is no automatic overflow, so if you pump in an excessive quantity of oil you will get smoking and excessive carbonisation. The pump itself is fixed to deliver a certain quantity of oil from the reserve tank, so maintaining a constant level. The hand pump is only to be used when you feel that the engine is short of oil or in a hilly country. (4.) There was no special petrol allowance in the last T.T. race. (In 1908 the allowance for a single was 100 m.p.g., for a twin 80 m.p.g.) The distance run was 225 miles, the course being  $37\frac{1}{2}$  miles long. The average speed of the winner was 49.49 m.p.h. (5.) Seventy miles to the gallon for this machine is quite good.

### READER'S REPLY.

#### Unsatisfactory Running.

With reference to "A.K.M.'s" query in your issue of August 2nd, page 121, I think perhaps I might be able to help him with a suggestion. Some time ago I was annoyed with the same thing happening to a fairly fast long stroke single-cylinder I had. The engine would pull quite well on the level, but on opening the throttle it would misfire, splutter in the silencer, and generally make a beast of itself until the engine stopped. That this stoppage was due to pre-ignition of sorts there is not the slightest doubt, for several times I deliberately let the engine knock itself out in order to see what happened. The last few strokes of the engine were in every case pre-ignition and back-firing to a terrible degree. Of course, I suspected either (a) heated plug, (b) portion of cylinder getting incandescent, or (c) carbon particle. I thoroughly cleaned the cylinder, looked in vain for a rough edge of metal, and fitted a Lodge racing plug. Result: No difference. I have looked through several books on motor cycling, etc., and have never yet seen an explanation of this somewhat rare (thank heaven!) occurrence. I cannot explain why it happened, but the cause of the trouble was that the condenser in the magneto was broken, therefore the points of the magneto became burnt out in no time, and on opening the throttle the spark appeared when and how it pleased. Sometimes it would appear when the piston was half up compression stroke, hence the terrible knock. When the magneto had been overhauled this trouble disappeared, and I would no longer stop on a small hill while someone on a baby two-stroke rattled past me, which, of course, as I was intensely proud of my machine, gave me the pip.—H. W. WILLIAMSON, LT., M.G.C.

*In answering these advertisements it is desirable to mention "The Motor Cycle."*

# MISCELLANEOUS ADVERTISEMENTS.

## PRICES.

**ADVERTISEMENTS** in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to **ILIFFE & SONS Ltd., and crossed**

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4.), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

## NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

## DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

## SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

## DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

## MOTOR CYCLES FOR SALE.

### Alldays.

**C**OLMORE Depots, Birmingham and Manchester, for immediate delivery of Allon 2-strokes. [0796]

**A**LLDAYS Allon, 2-stroke, 2-speed, new, just come from works; £40.—Sanders, 59, Bridge St., Castleford. [X3461]

**N**O Reasonable Offer Refused.—1916 Alldays Allon, 2-stroke, 2-speed; call after 5 p.m.—Broom, 77, Marylebone Lane, Oxford St., W. [6525]

**A**LLDAYS Allon, 2 1/2 h.p., 1917, 2-stroke, 2-speed, and clutch countershaft; £45.—W. and H. Motor Co., Ltd., 287, Deansgate, Manchester. [6509]

**A**RIEL, 3 1/2 h.p., 1917, 3-speed countershaft models, in stock.—Crow Bros., Guildford. [2562]

**C**OLMORE Depots, Birmingham, Manchester, Liverpool, and Leicester, for all models of Ariels. [0797]

**A**RIEL, 1914, with Millford sidcar, 3 1/2 h.p., 2-speed, decompressor, Bosch, B. and B. Jones speedometer, 3 lamps with generators, spares, in perfect condition; £35, or nearest offer.—20, Marlban Rd., Stoke Newington, N. [6441]

**A**RIEL, 1915, 3-speed, and clutch, 5-6 h.p., spring seat-pillar, Dunlop tyres, hood and screen, Lucas lamp and Cowey speedometer; £71/15; extended payments or exchange.—Service Co., 292, High Holborn, London. [X3773]

**A**RIELS.—Several new 3 1/2 h.p. 3-speed countershaft models actually in stock; clutch and kick starter, special spring seat-pillar, patent decompressor, etc., etc.; prices and terms on application.—Harrods New Motor Showrooms, 118, Brompton Rd., London, S.W.1. [6621]

### Auto-Wheels.

**19** 14 Auto-Wheel, very little used; £7/15, close offer.—Bertram, Gorebridge, Scotland. [X3726]

**W**ALL Auto-Wheel, just overhauled; bargain, 25.—Rumbrey, The Chestnuts, Norton, Malton, Yorks. [X3658]

**A**UTO-WHEEL, excellent condition, overhauled and July, with 2 1/2 gallons petrol; £6.—Roberts, 41, Hestercombe Av., Fulham. [6432]

**A**UTO-WHEEL, run about 500 miles, £8/10; another, £7/10; two gent's Raleigh cycles for same, £4/10 each.—21, Station Rd., Forest Gate, London, E. [6452]

**A**UTO-WHEEL, 1914, good running condition, nearly new Palmer tyre, price £6/10; with cycle if preferred, £8/10; splendid offer.—F. Putnam, Hazlemere, High Wycombe. [6542]

**C**HATER-LEA Lady-back Tandem, 21-24, 3-speed, with standard Auto-Wheel, just arrived; price on application.—Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green, N. [6306]

### Bradbury.

**19** 11 4 h.p. Bradbury 2-speed Combination, good running order; £25.—53, Brownhill Rd., Catford. [6595]

## MOTOR CYCLES FOR SALE.

## Bradbury.

4 h.p. Bradbury, 1913, splendid condition, £20; metal racing sidecar, £4/15.—35, Mowbray Rd., Brondesbury. [6523]

BRADBURY, 4h.p., 1914, coach combination, 3-speed, kick start, lamps and speedometer; £35, or exchange.—F.M., 22, Vale Rd., Finchbury Park. [6627]

## Brough.

BROUGH, 3½h.p., 1915, horizontal twin, painted grey, all accessories; £45.—Wertner, Tonbridge. [6521]

BRAND New 1917 Brough, 3½h.p., horizontal twin, 3-speed countershaft, lady's model, just delivered; suit lady or gent; £65.—Miss Reid, 171, Vernon Rd., Basford, Nottingham. [X3655]

## Brown.

BROWN, 3½h.p.; £12/10.—W. and H. Motor Co., Ltd., 287, Deansgate, Manchester. [6506]

## B.S.A.

B.S.A., 4½h.p., brand new, actually in stock.

B.S.A. 4½h.p. 1915 Combination, indistinguishable from new; £60.—Percy and Co., 337, Euston Rd., London. [6639]

COLMORE Depots 261, Deansgate, Manchester, for immediate delivery of B.S.A. [0798]

IF You Want a B.S.A., write us for motor cycle list.—Walbro Motor Co., Ely, Cambs. [X3754]

B.S.A. New 1917 Model K's in stock; £64.—Colmore Depot, B.S.A. Agents, 211, Deansgate, Manchester. [0888]

B.S.A., 1914, semi T.T., in good running order; bargain, 25 gas.—441, Brighton Rd., South Croydon. [6495]

NEW 1917 B.S.A., 4½h.p., Model K, the last one left.—Elce and Co., 15-16, Bishopsgate Av., Camomile St., E.C.3. [0481]

B.S.A. 1916 Combination, almost new, and all spares; write for particulars; price £68.—Turner, 21, Welsh Rd., Queensberry, near Chester. [6576]

NO Reasonable Offer Refused.—Late 1913 B.S.A., 2-speed, equivalent to kick starter, new tyres, with or without sidecar; call after 5 p.m.—Broom, 77, Marylebone Lane, Oxford St., W. [6524]

B.S.A., 1916, Lucas lamps, mechanical horn, 500 miles, fitted Phoenix sidecar chassis and Enfield O.B. body, excellent combination; worth £70, take £65.—Williams, B.V.C., Parsons Green Lane, S.W. [6490]

B.S.A. 4½h.p. 1917 C.B. Combination, 3-speed countershaft, kick starter, Lucas lamps, generators, horn, chain driven, ridea 100 only; cost £84, accept £73, bargain.—Smith, Charlton Villa, Staines Rd., Bedford, Middlesex. [6455]

1916 B.S.A., chain-belt, 3-speed countershaft gear, 4½h.p., suitable for sidecar work; price only 46 gas.; undoubtedly the cheapest B.S.A. in England to-day.—Julius, 84, Broad St., Reading. Biggest light car and motor cycle dealer in the South. Phone: 1024. [0916]

## Calthorpe.

IF You Want a Calthorpe, write us for motor cycle list.—Walbro Motor Co., Ely, Cambs. [X3755]

COLMORE Depots, Birmingham, Manchester, and Liverpool, for Calthorpe motor cycles. [0799]

1916 Calthorpe, 2-stroke, excellent condition; 21 gas, bargain.—436, Whitehorse Rd., Tottenham Heath. [6492]

1916 2½h.p. 2-speed Calthorpe-Jap, in splendid condition, lamp, etc.; £30.—Simister, Jordnagate, Macclesfield. [X3716]

CALTHORPE-J.A.P., 1916, 2½h.p., Enfield 2-speed; owner called up.—Chapman, Glewosa, Honey Lane, Waltham Abbey. [6377]

CALTHORPE-J.A.P. Lightweight, 2½h.p., Enfield countershaft 2-speed gear.—Motor Exchange, Horton St., Halifax. [6585]

CALTHORPE, 1917, J.A.P., latest model, brand new, Enfield 2-speed, in stock; 38 gas.—Wilkins, Simpson, and Co., 11, Hammersmith Rd., London. [6464]

CALTHORPE-J.A.P., 2½h.p., late 1915, Enfield 2-speed gear, lamps, splendid condition; £27.—Apply after 8 p.m., 5, Trilock Rd., Tottenham, N.17. [6572]

CALTHORPE, 1917, 2-stroke, Enfield 2-speed, latest model; 35 gas., brand new, in stock.—Wilkins, Simpson, and Co., 11, Hammersmith Rd., London. [6465]

CALTHORPE, 2-stroke, Enfield 2-speed, new, but slightly shop-soiled; special bargain, 30 gas.—Wilkins, Simpson, and Co., 11, Hammersmith Rd., London. [6466]

2½h.p. Calthorpe, 2-stroke, Enfield 2-speed gear, perfect condition throughout; 20 gas.—Parker, 11, Claricarde Gardens, Notting Hill Gate, London, W. [6403]

CALTHORPE-J.A.P., 1915, 2-speed, 2½h.p., only used 6 months, owner at sea, £28/10; also three brand new 1917 models actually in stock.—Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green. [6304]

## The "GRADO" Paraffin Vaporiser.

Motor Cyclists! Here is a device which will enable you to run on paraffin and get results equal to petrol. It is designed by a practical engineer and has been well tested. It fits between the engine and carburettor, and is connected to the silencer pipe by the clip illustrated. An injection of petrol through the tap on top starts your engine. Paraffin then does the work.

This is the New Model.

PATENT No. 13113.

It is just what you require to-day.

The price, all complete, is **35/-** Postage 6d. extra.

Delivery from stock. Order now, stating the outside size of inlet pipe.

## The "GRADO" MULTI-PULLEY.

PATENT No. 27485/13 and 6612/14.

Is simple in construction. Nothing to go wrong. Fits any standard belt-driven machine. Just half a turn of the handle changes from top gear to free engine. So simple. Starts you like a car. The low gear gets you through traffic. The high gear saves fuel and gives you speed. The middle gears are there when you want them. The price, complete, for Triumphs, Bradburys, etc., is **£3 3s**. Ball-thrust model, which we recommend, **£4**. Light-weight models from **£2 10s**. Recessed pulleys, **10/-** extra. Postage **2/-** extra. Delivery from stock. Write for Catalogue.

Pulley fitted to machine.

## The "GRADO" HEATING JACKET.

PROV. PATENT No. 8124/1917.

This is the simplest and most effective way of heating the fuel. It does the trick in the right place. Simply fits over the carburettor, and allows of hot exhaust going all the way round it. There is no need to heat your fuel two feet away. Do it on the job by the "Grado" Heating Jacket. Made for A.M.A.C., Senspray, B. & B. Triumph, etc.

State diameter of float chamber, or send carburettor and we will return with one fitted. Order to-day.

EXHAUST INLET

"GRADO"

HEATING JACKET

LEVIS 1917 Popular, latest model, brand new; £32.—Wilkins, Simpson, and Co., 11, Hammersmith Rd., London. [6467]

LEVIS, 2½h.p., lamp, horn, speedometer; £17; excellent machine.—Webster, 18, De Crespigny Park, S.E.5. After 6 p.m. [6539]

LEVIS, 2½h.p., 1915, 2-stroke, head lamp, generator, rear lamp, good tyres, fully equipped; bargain, £24.—Advertiser, 156, Gt. Portland St., W. [6609]

## Matchless.

MATCHLESS Motor Cycles: no quicker delivery obtainable than from Colmore Depots. [0881]

MATCHLESS, 1913, 8h.p., and coachbuilt sidecar, 2-speed, kick start, splendid condition; £50.—60, Lime Grove, New Malden, Surrey. [X3668]

MATCHLESS, 1913, 6h.p. twin J.A.P., free engine, in real nice order and condition; £28.—Percy and Co., 337, Euston Rd., London. [6643]

MATCHLESS, 6h.p., 3 speeds, clutch, underslung C.B. sidecar, smart; £40, offer; exchange.—18, Gower Rd., Peckham. Appointment. [6623]

MATCHLESS 8h.p. Combination, 1917, 8B2 (not military model); never been ridden; what offers? 66, Howarth Rd., Plumstead, S.E.18. [6458]

MATCHLESS, 1915, hood, screen, speedometer, a most gorgeous machine, guaranteed date and condition; £82.—Write only, 51, Maplethorpe Rd., Thornton Heath, S.E. [6373]

MATCHLESS 1915-16 8B 7h.p. Combination, with heap accessories, child's seat at rear, tip-top order; £25.—Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green. [6500]

MATCHLESS 1917 Combination, 8h.p., 3-speed, clutch, and kick starter, detachable wheels, including spare wheel, new; £120; extended payments or exchange.—Service Co., 292, High Holborn, London. [X3784]

## Mancunian.

MANCUNIAN, 2½h.p., 2-speed; £35.—W. and H. Motor Co., Ltd., 287, Deansgate, Manchester. [6502]

## Minerva.

MINERVA, 3½h.p., vertical m.o.v. engine, coil ignition; £31/5.—Motor Exchange, Horton St., Halifax. [6593]

## Moto-Reve.

MOTO-REVE Lightweight, mag., Druids, Amac, vaporiser, running on paraffin, perfect condition; £15.—Aldis, 39, Eastward Hol, Leiston, Suffolk. [6487]

## Motosacocha

3½h.p. Motosacocha, M.A.G. engine, Enfield 2-speed, 2 lamps, etc., good condition, fine solo; £28.—Joseph Pearson, Whittington, Epsom. [6514]

EXCEPTIONAL Opportunity.—Brand new 1917 Motosacocha and sidecar, 6h.p. M.A.G. engine, 2 speeds, etc.; cost £88 week ago, sacrifice £78 for spot cash; any trial or examination welcomed.—Apply, Revell, Butcher, Sheffield Rd., Chesterfield. [X3801]

## New Hudson.

NEW HUDSON 6h.p. Twin Combination, 3-speed, 1914; £60.—W. and H. Motor Co., Ltd., 287, Deansgate, Manchester. [6503]

New Hudson, 1912, 2½h.p., 3-speed, clutch, fine order; £16.—Smith, 16, Haverstock Hill, opposite Chalk Farm Tube. [6364]

1915 New Hudson, 2½h.p., 2-speed, free engine, little used; owner joined up; £27/10.—T. Owen, Pool House, Hedsdesford. [X5996]

NEW Hudson 2½h.p. Lightweight, single speed, as new; £20, or exchange for combination.—F.M., 22, Vale Rd., Finsbury Park. [6626]

NEW Hudson, 2½h.p. J.A.P., 3-speed hub, clutch, excellent condition, lamps, etc., complete; £25.—R.N.A.S., 44, Dodington Grove, Battersea Park, S.W. [6386]

## New Imperial.

NEW Imperial, 1917, 2½h.p., 3½h.p., 6h.p. models, in stock.—Crown Bros., Guildford. [2563]

COLMORE Depots, Manchester and Leicester, for immediate delivery of New Imperial motor cycles. [0805]

NEW Imperial-Jap; immediate delivery all models.—Exeter Motor Cycle Co., Ltd., Bath Rd., Exeter, and Tavistock Rd., Plymouth. [0839]

NEW Imperial, 1917, 2½h.p., 2-speed, in perfect condition, lamps, horn, spare belt, 120 m.p.g.; £32.—Box 14,237, c/o The Motor Cycle. [6582]

1914 New Imperial-Jap, 2½h.p., 2-speed, chain-cum-belt, tyres excellent, mechanically perfect, good as new; £24.—24, Plassy Rd., Calford, S.E. [6461]

NEW Imperial-Jap, 1915, 2-speed gear, in splendid order, with lamp and horn; trial given; £24 cash, no offers.—Hall's Garage, Ltd., Stevenage, Herts. [6415]

NEW Imperial, 2-speed, new, 39 gns. 2-speed, clutch, and kick starter, 46 gns. extended payments or exchange.—Service Co., 292, High Holborn, London. [X3782]

## MOTOR CYCLES FOR SALE.

## New Imperial.

NEW Imperial-Jap, 1917, 2½ h.p., 2-speed, extra tank, lamps not been lit, tyres unpunctured, excellent condition; £32.—Richardson, Kilm Bank, Milnrow. [X3687]

NEW Imperial-Jap, 2½ h.p., 1915, 2-speed gear box, new tyres and belt, just thoroughly overhauled and re-ennamelled; £27/10.—21, Station Rd., Forest Hill, London, E. [6451]

NEW Imperials, 1917 models, for immediate delivery, No. 1 39 gns., No. 2 46 gns.; two new 1916 models No. 1 at £38.—Colmore Depots, 211, Deansgate, and 31, Beeshaw St., Liverpool. [6886]

NEW Imperial, 2½ h.p., 2-speed, 38 gns.; actually in stock for immediate delivery; extended payments arranged.—Harrods Stores, Ltd., New Motor Showrooms, 118, Brompton Rd., London, S.W.1. [6620]

1916 New Imperial-Jap, absolutely new, never been used; first cheque for 52 gns. secures this bargain.—Julians, 84, Broad St., Reading. Biggest light car and motor cycle dealer in the South. Phone: 1024. [6915]

NEW Imperial-Jap, new May, 1916, unused winter and wet weather, Brooks B170, Jones speedometer, extra tank, metal fore and undershield, P. and H. large head light, spare tube (unused), condition excellent; £30.—Motor House, Brompton, Chatham. [6409]

2½ h.p. New Imperial-Jap, late 1916, not ridden 200 miles, as new condition, E.I.O. mag., Amco carburettor, Lycett saddle, Dunlop tyres and belt, Druid forks, horn, and lighting set, absolutely as new; £31, no offers.—W. Thralfall, Beechfield, 23, Cope St., Bamsley, Yorks. [X3606]

## Norton.

NORTON Big Four, 1916, 3 speeds, combination, in real good order and condition; £65.—Percy and Co., 337, Euston Rd., London. [6640]

1914 4½ h.p. 3-speed Norton and Gloria sidecar, with lamps, speedometer, horn, etc., in splendid condition; £56.—Simister, Jordangate, Macclesfield. [X3715]

## N.S.U.

1914 Rear Sprung 6½ h.p. N.S.U., 2 speeds, coach-built sidecar, lamps, all accessories, condition perfect; worth £60; no reasonable offer refused.—17, Uxbridge Rd., Hawwell, Middlesex. [X3602]

## O.K.

O.K. Juniors.—Call and inspect at the N.W. district agent, F. J. Youngs, 2-3, The Parade, Kilburn. [6910]

O.K. Junior, Mark IV, standard, new; 38 gns.; extended payments or exchange.—Service Co., 292, High Holborn, London. [X3776]

1915 O.K. Lightweight, 2-speed countershaft, almost new; bargain; £25/10; private owner.—Harris, 56, Chestnut Rd., West Norwood. [6485]

O.K., 2½ h.p., 2-speed, completely equipped, and in excellent condition; £21, no offers.—Longman Bros., King St., Acton. Phone: 1578 Chiswick. [6554]

## Omega.

1915 2½ h.p. Omega, 2-stroke, B.B. carburettor, E.I.O. mag., in good condition; £16/10.—Whale, Bacombe Warren, Wendover, Bucks. [6421]

## Peugeot.

6 h.p. Twin Peugeot, free engine combination, very fast, sports bike; any trial here; £30, or offers.—Goodall, 2, St. John's Terrace, Kingston Vale, Patney. [6550]

## Precision.

PRECISION, 1913, 4½ h.p., 3 speeds, and coachbuilt sidecar; £29/10.—Motor Exchange, Horton St., Halifax. [6592]

## Premier.

PREMIER, 1913, 3½ h.p., countershaft gear, and coach sidecar; £37/10.—Motor Exchange, Horton St., Halifax. [6588]

PREMIER, 1913-1914, 3½ h.p., chain-cum-belt, 3 speeds, free engine, splendid condition; bargain; £24.—12, Roslin Rd., St. Acton, W.3. [X3666]

PREMIER, 1916, 3½ h.p., 3-speed countershaft gear, £45; 1916, with sidecar, 3½ h.p., spare tank, £69; extended payments or exchange.—Service Co., 292, High Holborn. [X3770]

2½ h.p. Premier, at Ascot, in perfect running order, as new, long exhaust, electric head and tail, horn, spare belt, spare tyre, tool kit, 125 m.p.g.; £25, or good offer.—Box 1,118, c/o The Motor Cycle. [X3664]

1913 Premier, 3½ h.p., wicker sidecar, N.S.U. 2-speed, F.E., new 1916, Bosch, B. and B., auxiliary exhaust and rear wheel new, tyres as new, Lucas lamps, no winter use, splendid hill-climber, magnificent condition, spares; inspection, trial; £26/10.—Avery, Matlock Bath. [X3808]

## Quadrant.

QUADRANT 4 h.p., 1916 Combination, 3-speed, all-chain drive; £60.—W. and H. Motor Co., Ltd., 287, Deansgate, Manchester. [6508]

3½ h.p. T.T. Quadrant, Bosch mag., B. and B. carburettor, hot air intake, good tyres, runs well on paraffin, excellent condition; £13.—Kent, Sussex Lodge, Beckingham. [X3724]

## Forwards fail?—Never!

They are so scientifically correct in construction that failure is impossible. The most destructive conditions only go to prove how true this is of Forward Fasteners.

All the experts and manufacturers fit them—follow their lead.

## Forward Motor Co.,

35, Forward Works, Summer Row, Birmingham.

THE ZILLA ALL WEATHER BELT  
No Slip. More Power, Less Petrol, No Fastener Required.

## MOTOR CYCLES FOR SALE.

## Radco.

RADCO, 1914, 2½ h.p., single speed; £12/10.—Lamb's, 151, High St., Walthamstow, and 60, High Rd., Wood Green. [6305]

## Rex.

REX, 2½ h.p., 3 speeds and free engine, Bosch mag.; £24/10.—Motor Exchange, Horton St., Halifax. [6589]

REX 6 h.p. Combination, Bosch mag., Mabco clutch, powerful machine, in good condition; £20.—Searle, 98, Walpole Rd., St. Yarmouth. [6425]

REX Motor Cycle and Sidecar, 1913, 5-6 h.p., 2 speeds, free engine; £38; extended payments or exchange.—Service Co., 292, High Holborn, London. [X3764]

REX, 1911-12, 6 h.p., B. and B. carburettor, mag., Druid spring forks, new tyres, just overhauled at Rex works; any trial; £17.—7, Talbot St., Kidderminster. [X3607]

1914 Rex de Luxe Combination, hood, screen, 3-speed chain drive, not used for 15 months, in new condition; sacrifice £60, lowest.—Varrall, Grocer, Amen Corner, Totting. [6405]

## Rex-Jap.

6 h.p. J.A.P. (Rex-Jap), complete with coachbuilt sidecar, 2-speed gear, spring seat, in splendid condition; £60.—Turpin, 29, Preston Rd., Brighton. [5500]

## Rover.

1917 Rover and Sidecar, first-class order; £85.—On view Tye's Garage, Sevenoaks. [6482]

If You Want a Rover, write us for motor cycle list.—Walbro Motor Co., Ely, Cambs. [X3746]

ROVER, T.T., brand new, actually in stock.—Percy and Co., 337, Euston Rd., London. [6641]

COLMORE Depots, Birmingham and Manchester, for quickest delivery of Rover motor cycles. [6883]

ROVER, 3½ h.p., clutch model, thorough order, engine just overhauled; £21.—S., 17, Johnson St., London, W.8. [6400]

3½ h.p. Rover and Sherbourne sporting sidecar; rare bargain; sacrifice; called up; £32.—Fairhurst, Rylance Row, Wigan. [X3600]

ROVER Motor Cycles, 1917 models from stock; £74/10; two only; first cheque secures.—Colmore Depot, 211, Deansgate, Manchester. [6887]

ROVER, 1915, countershaft, 3 speeds, clutch, Lucas accessories, tools, good condition; £46; owner enlisted.—Fox, 600, Fulham Rd., Fulham. [6401]

ROVER, 3½ h.p., 2-speed, all accessories, and tools equal new; £30; with sidecar £35; runs on paraffin.—Box L4,238, c/o The Motor Cycle. [6581]

ROVER and Sidecar, 1916, 3½ h.p., 3-speed, perfect condition, little used, speedometer, 3 lamps, horn, complete tool kit, overalls, and petrol; £50.—5, Gairloch Rd., Camberwell. [6545]

ROVER, 1916½, 3½ h.p., countershaft model, full accessories, tools, F.E.S. combined acetylene electric lamps, perfect condition, unscratched; £62.—Ratcliffe, Cleveland Rd., Lowestoft. [6435]

## Royal Ruby.

ROYAL Ruby, 2-stroke, single speed, new; £29/10; extended payments or exchange.—Service Co., 292, High Holborn, London. [X3781]

1916 Royal Ruby, 2-stroke, with light sidecar, extra fast, powerful; £24, or separate.—Thorpe, Whitehorse Rd., Thornton Heath. [6493]

DEC., 1916, 2½ h.p. Royal Ruby, 4-stroke, 2-speed, J.A.P. engine, as new; owner on active service; bargain; £28.—Apply, 195c, Cheltenham Rd., Bristol. [X3797]

## Rudge.

RUDGE Multi, 1916, almost new; £45.

RUDGE, I.O.M., T.T., as new; £50.

RUDGE, 1914, N.S.U. 2 speeds, in nice condition; £23.—Percy and Co., 337, Euston Rd., London. [6630]

If You Want a Rudge, write us for motor cycle list.—Walbro Motor Co., Ely, Cambs. [X3748]

RUDGE, single, 3½ h.p., 1914, good condition; £18.—Mappin, 22, Norris Rd., Sheffield. [X3589]

1914 Rudge Multi, 5-6 h.p., cane sidecar, fine condition; £35, or near offer.—Bull's, Westgate, Mansfield. [X3663]

RUDGE Multi 3½ h.p., 1913 Combination; £43.—W. and H. Motor Co., Ltd., 287, Deansgate, Manchester. [6504]

1913 Rudge and Sidecar, 3½ h.p., N.S.U. 2 speeds, not used last 2 years; £22.—Clough, New Hall Hay, Rowntestall. [X3585]

RUDGE, 1914, clutch model, kick start, splendid condition, fast, smart, and economical solo mount; £30.—Mary's Lodge, Grove Rd., South Woodford. [6544]

1914 Rudge, T.T. Model, 3½ h.p., nearly new tyres, thoroughly overhauled, in fine running order, very little wear; £25.—Cain, 38, Briton St., Leicester. [X3721]

3½ h.p. Rudge, free engine, £14; also 3½ h.p. Premier, free engine, 3-speed gears, with box carrier and sidecar; £24; splendid condition; seen after 7 p.m.—W. Haynes, 252, East St., Old Kent Rd., S.E. [6535]

## Clean Engines.

THE old proverb concerning the matter of "cleanliness" is no less applicable to motor cycles and their riders than to other affairs of life. A dirty machine is hardly a pleasant thing to look upon, and it has a nasty habit of communicating its filth to the man handling it. Dirt, therefore, is a very poor advertisement for the pastime, and it behoves manufacturers, in designing after-war models, to do their utmost to keep their products as clean as possible.

The motor cycle is prone to dirt of two kinds—oil thrown from the engine and mud collected from the road. The latter evil has received a good deal of attention of late, with the result that mudguards have been greatly improved, but there is still much to be done in this respect. A small undershield is a very great improvement, as it not only keeps the rider clean, but further protects the engine from mud and grit. The motor cycle engine works in a pre-eminently exposed position. Most of the time its external moving parts are working in a cloud of grinding material. This, of course, applies to many machines which have unprotected tappets and valve stems.

We now come to the other evil—the leakage of oil. To make a crank case or gear box absolutely oiltight is a very difficult matter which has been very rarely accomplished. In many cases there are far too numerous excrescences, nooks, crannies, and corners in which mud and oil mixed collect, and this is extremely difficult to extract, even with the aid of a stiff brush and frequent applications of paraffin.

The crank case, therefore, which is bound to get a little oil on it, owing to the lubricant gradually working past the tappets and bearings, should be devoid of inaccessible corners and raised lettering, and should be as neat as possible. Where it is desired to strengthen the aluminium by means of lugs, corners

should be rounded so that they can be easily wiped over.

## Cleanliness and Depreciation.

Projecting nuts are a nuisance to the man who takes a pride in his machine. Though they are perhaps a more satisfactory means of securing the two halves of the crank case than the countersunk screw head, still the latter has many advantages. A crank case fitted with a proper relief valve, which passes any surplus oil clear of the machine, is a great blessing, and attention should be paid to this point.

There is one method of lubrication which renders it quite impossible to keep an engine clean, and that is the petroil system, and, though it has been acknowledged to be the most satisfactory method of lubrication for a two-stroke, it is extremely bad from the rider's point of view. The oily mixture which leaks from the filler cap and the carburetter float chamber gradually spread over adjacent surfaces, and eventually reaches the rider's overalls—a very serious disadvantage to all those who take pride in their personal appearance.

It is up to the manufacturers, then, to aim at external cleanliness, for many riders have not much time to spend in cleaning and polishing; while it is an entirely hopeless task to attempt to keep a machine decent which sheds oil from its tappets, its timing case joints, and sundry other cracks and crevices.

It is a short-sighted policy on the part of a manufacturer to render a machine difficult to clean. Those who are careless in this respect get a very poor advertisement for their products, which always look dirty, because the motor cyclist will not take the trouble to look after them properly. If the manufacturer makes the rider's task easy the latter will not shrink from performing it. If, however, the cleaning job is too difficult a one the rider will naturally shrink from his task, with the result that the machine is dirty, and the presence of dirt almost undoubtedly proves neglect.

## Noisy Carburetters.

Valve Clatter depends not only on Tappet Design, but upon the Carburetter and Induction Pipe.

THE writer has many times proved to his own satisfaction that quite a considerable amount of the clatter audible to the rider of a machine emerges into the open air *via* the carburetter. To give a single illustration. Recently I have been riding to and from business a two-stroke lightweight, which, comparing it with other machines of a similar type, always struck me as unnecessarily "fussy." Wishing to adapt the machine for the consumption of heavy fuels, I fitted, a few days ago, a hot air intake with a suitable form of muffle, and, remounting, I was at once struck by the soothing quietude of the engine. Evidently, then, half the clatter of former days had emerged through the carburetter, while the extension now fitted acted as a carburetter silencer! It further explains why the metallic clatter of the engine increased in proportion to the throttle opening, for the further the throttle was opened the greater the volume of sound allowed to pass from the scurrying internal mechanism.

I remember that on another occasion I utilised part of an old horn as a hot air intake, the funnel-shaped extension drawing its supply from the cylinder fins. This fitment converted the carburetter into a miniature gramophone, so that the clatter of the valves at the other end of the induction pipe was so much accentuated as to be almost deafening. On opening the throttle and allowing the noise to pass out freely, one obtained an impression of wonderfully improved acceleration; as a matter of fact the acceleration was the same as before, and one was merely reminded of every response to the throttle by the fact that the throttle not only governed the speed but also the noise!

### Carburetter Design.

During various tests of various carburetters I have noticed that some are distinctly "more silent" than others; that is, the design of some—accidentally, no doubt—is such that it baffles the internal racket of the engines, while others, on opening the throttle, lay the internal mechanism open to the air. It must be remembered that, in the case of a four-stroke, two or four valves are clattering up and down on their seatings at the immediate end of the pipe to which the

carburetter is fixed, and by opening the carburetter their rattle may be entirely exposed to the air—save for a filtering gauze. With a steam engine one hears no internal clatter of piston rings, etc., because the induction of a steam engine is closed, jointed, and sealed, and only by holding one's ear to the induction pipe (which is bad for the ear) does one become aware of the internal clatter of the cylinder.

### Deadening Sound.

Let us take it, then, that quite a considerable amount of the clatter audible to the rider travels along the induction and escapes *via* the carburetter. It is conducted to the open not only by the "air" contained in the induction pipe, but by the induction pipe itself, which is a veritable sounding box. I stand steadfast in the belief that the ultimate silencing of a motor cycle engine depends not so much in any radical alteration in design, as in the employment of sound-deadening materials wherever possible. Even the thin fibre packing between the crank case and the cylinder helps to deaden the metallic ring, and if you wish to illustrate this point still further, just fix the lid of a tin between the lock-nuts of your engine-shaft sprocket, and you will find that the tin re-echoes and accentuates every metallic note of the engine. Then place a fibre washer on either side of the tin, so that it is gripped between the sound-deadening materials, and it has no effect upon the noise produced.

The metal induction pipe merely acts as a sound conductor, and therefore the question arises, Why make the induction pipe of metal? True that it has valuable heat conductive properties, but vapours condense more readily on a metal surface than they do on, say, the surface of fibre.

Induction pipes made of some suitable fibrous material would, I am sure, not only have the effect of deadening the noise of the valves, but would lead to better fuel consumption. If a hot air intake were fitted, the induction pipe would absorb practically none of the warmth from the incoming charge, which would therefore gain the cylinder in a dry state. The fibre induction pipe would eliminate air leak, as no expansion sleeve would be necessary. **WHURNSIDE.**

By using this type of air intake the writer was convinced that a great deal more engine clatter is conveyed *via* the carburetter than is generally realised.

# Occasional Comments

by "Ixion"

## R.F.C. Recruits.

SOME of our readers have expressed disappointment and perplexity that it is not very easy to enlist for temporary service in the R.F.C. I have no official information on the subject, but any thoughtful person will recognise that, whatever happens to other arms of the service, the Flying Corps will have to be maintained at something approaching full war strength unless or until international limitation of armaments is established. Its importance to this country in particular will very soon exceed that of the Army or Navy. This fact would supply ample justification for any policy which aimed at getting the cream of our young men into the flying services, and keeping them there for a term of years. The point is emphasised when we reflect that practically every job in the R.F.C. is a technical job, and usually one at which no man can become really efficient on the short service system, unless he chances to have had prolonged civilian experience of somewhat similar work.

## Oil Grades and Smoky Exhausts.

PERHAPS Mr. Brooker, or some other oil expert, will comment on the following experience. I own a certain engine, on which I have meekly used a particular lubricant for 5,000 miles, in childish reliance on the maker's recommendation. It proved itself a champion plug-sooter, and I began to fine down the oiling to terms of cubic millimetres. You remember the Greek philosopher who had just taught his horse to subsist without food when it died? Well, I had just cured that engine of its plug-sooting propensities when it seized. So in the next spasm I utilised adapters to hoist the plugs out of the oil shower. One day I ran short of oil on the road, and was compelled to buy some of that thick sludgy stuff which everywhere passed as "air-cooled" oil until the castor dopes came in. I filled up with this semi-solid stuff rather timorously, and noticed, to my joy, that the exhaust immediately ceased to be visible. Out came the plug adapters, and since then I have used no other oil, plug-sooting has ceased. But I am puzzled. I suppose my pistons have at least 3-1,000in. clearance at their tightest point, and such a clearance must be equally an open path to two such diverse lubricants as Price's "A" and "Huile de Luxe." The cylinder walls and piston skirts are therefore all aslop with oil in both cases. Then the spring of the rings permits the thin oil to squeeze past, but not the thick. Or, alternatively, the heavier oil gets splashed less than the thin! I cannot see daylight through this quaint little fact, and am, on the whole, inclined to wonder if my piston rings gummed into the grooves on the thin oil and leapt out like unicorns when I used the thick stuff! Wish I were a pukka expert and could solve all my worries on half a sheet of notepaper with half a dozen assorted Greek and English capital letters and ten places of decimals.

## Oily Plugs on Efficient Engines.

A NUMBER of correspondents continue to enquire for a sparking plug which will stand "revs." and yet won't oil up. The answer is that no such plug exists—at any rate, for us. The R.F.C. and R.N.A.S. may have some, though I doubt it, as their engines seldom exceed 1,600 r.p.m. But there is no plug sold to the public which will keep cool on a super-efficient engine and at the same time burn off any surplus oil which may be thrown on its points. The rider for whom this problem has become acute has two alternatives open to him. He may mount his plug (or plugs) in a screwed adapter, which will hoist it half an inch or so higher out of the oil-splash zone and give it a better chance to keep clean. Or, alternatively, he may perfect more precise lubrication methods. Makers do not deliver machines which necessarily soot up a plug every few miles, but they do—most reprehensibly, of course—sell machines which soot plugs unless the user is very, very accurate alike as regards (a) grade of oil; (b) amount of each charge, or rate of drop, as the case may be; (c) varying the oil feed to suit the load and work.

## The "Unit" System.

66 CHINOOK" has dealt ably with the pros and cons of the engine-cum-gear box unit system, and I am wholeheartedly with him. To my mind it possesses two very great merits from the standpoint of reliability and wear. A manufacturer may turn out a splendid engine and a splendid gear box as separate units, but he is certain to have a high percentage of the gear boxes returned to him for repair after mileages ludicrously inferior to those which his testers obtain. The trouble usually arises from one of two causes: Motor cyclists are careless customers, and it is a tedious and messy job to introduce lubricant into an astern gear box through the official orifice, which is usually small and inaccessible. Insufficient oil is inserted, and a lot of it gets squeezed out. Many of the gear boxes issued by some makers come back with injuries due to under-lubrication after quite brief service. Secondly, the amateur is trusted to adjust the chain drive between separate engines and gear boxes, and he is not always trustworthy. Some makers guard against the amateur's tendency to dis-align his gear box; on one Matchless model, a circular gear box can be rotated eccentrically; on one Douglas model the gear box alignment is ensured by a slide way. But on too many machines the gear box is slung from hanger-bolts, which are a loose fit in a slotted bracket, and many amateurs lock up such gear boxes on the cross. Both these dangers are eliminated by the adoption of the "unit" system, which provides for automatic lubrication and inevitable alignment. Thus the system endows the purchaser with a more reliable machine, and protects the manufacturer from much trouble with his less clever clients.

# MOTOR CYCLE AND CANOE IN THE SHETLANDS

A unique home-devised attachment to widen the health and pleasure giving scope of the motor cycle, and particularly adaptable to such regions as the Shetlands, where there is such a variety of places where one can indulge in canoeing. The author's canoe was made interchangeable with the sidecar body, enabling him to use it in many of the lochs and voes which otherwise he could not have explored.

**T**HE outfit to which I have made the unusual additions about to be described is a 1914  $3\frac{1}{2}$  h.p. P. and M. with basketwork sidecar attachment. Regarding this machine I cannot speak too highly, its power and reliability being all that one might wish for—even in this region of hills and where roads are not of the best.

In order to adapt the sidecar for carrying the canoe, as shown in the illustrations, my first act was to add an extra leaf to each of the springs, and it was necessary, of course, that the sidecar would mount either the standard body or the canoe at will. My next move was to alter the bars that connect the springs, and on which the sidecar body is mounted, in such a way that they slipped in or out without disturbing the springs themselves, and by simply removing the nuts at the ends of the rods.

It required a good deal of thought before a suitable plan was hit upon, but finally I got over the difficulty by shaping a thin flat bar of iron to fit the inside of the canoe. The ends of this strip of iron protrude above the gunwale of the canoe on either side, and have holes in them which register exactly with the holes in the ends of the springs, so that with the canoe in position the two can be held together simply by means of bolts having thumb nuts.

This was all right for the back connection, but the front ends of the springs being much lower required the making of a special detachable bar raised in the centre sufficiently to keep the canoe parallel, and fastened in the same way as the back connection already described.

## Making the Canoe.

As regards the canoe itself, as this is specially adapted to the work to which it has been put, a few

notes regarding its dimensions, etc., may be of interest. The length of the canoe is 11ft. overall, but it could safely have been made 12in. to 18in. shorter, as this would have eliminated a good deal of the whip which now takes place when cornering. The width of the canoe is 21in., and it is 12in. deep amidship. It is constructed from sheets of three-ply wood, the bottom being  $\frac{1}{4}$ in. thick, sides and back  $\frac{3}{16}$ in. It is built up of six longitudinal stringers of elm,  $1\frac{1}{8}$ in.  $\times$   $\frac{3}{4}$ in., steamed and bent to shape. The bottom is in three equal sections, the centre part being flat, while the others slope gradually upwards to the sides and ends, and finally taper off. All the seams are set in white lead and fastened with brass screws and copper nails, while the bottom is covered with thick cotton. The canoe is coated inside and out with several applications of oil paint, and finished in green Robbialac, lined black. The result is a perfectly watertight canoe, having a total weight, with all accessories aboard, of approximately 1 cwt. The cost of material was about £7, war time prices.

## Fitting the Floats.

Coming now to some of my own experiences, which date back with canoes to the old simple canvas-built type with strips of cheese boxes for ribs, the following notes regarding the outfit may be included. I have found that on every sidecar I have measured, the distance between the mudguard stays and the connections of the sidecar chassis is not sufficient to enable one to swing a canoe having a sufficient width to render it safe on the water. I therefore put into practice an old idea among outriggers, that of employing two light boat-shaped floats projecting from either side of the canoe, the metal parts of this arrangement being the two halves of an old F.N. stand—arranged to

**Motor Cycle and Canoe in the Shetlands.—**

screw on to the same nuts that fasten the canoe on to the chassis, this addition rendering the canoe quite safe even with two passengers on board in a fairly choppy sea.

**A Novel Method of Propulsion.**

The security of the little craft now tempted me to try the more exciting sport of sailing, and, as many readers are doubtless aware, the delightful sensation of sailing in a canoe, with its ever-present touch of risk, is only equalled by going all out on a fast motor cycle.

Finally, as a change from sailing, and also from the rather tedious work of paddling in calm weather, I constructed a small ball bearing hand-driven propelling mechanism, which is capable of driving the canoe at a fair speed. As a detailed description of this and the all-important steering gear involved would take up too much space, I will leave the subject in order to deal with the more fascinating pastime of motor cycling in the Hundred Islands of the Shetlands.

of all makes and various dates of manufacture. A friend of mine, a traveller, has the creditable mileage of over forty thousand on his early 1913 2¾ h.p. Douglas, which looks good for many thousands more.

At the present time—owing to the petrol restrictions and the fact that the bulk of the male population is with the Colours—motoring here, as elsewhere, has greatly diminished, but with the return of brighter times I can think of no better place for the tired campaigner to rest and recuperate than these quiet northern isles, where the fresh healthy ozone breezes

Where the mobility of the motor cycle is an advantage. The canoe can be taken to the water's edge and lifted from the chassis directly to the water. (Inset) When the canoe is used for sailing the floats act as stabilisers; in this view the hand-propelling gear is in action.

Two or three of the larger isles only, together with the mainland, are adapted to motoring; the roads are fairly good but hilly, and as no part of the land is more than three miles from some arm of the sea, the roads wind about considerably, with not a few hair-pin bends. There are no trains or trams in the Shetlands; nor are there ever likely to be, consequently motor cycling in the isles has very much come to stay. Business men and others have not been slow in finding out the extreme usefulness of their mounts, which are

will soon vanquish the effects of poison gas, etc. In the summer one can enjoy the novelty of cycling until midnight *without lamps*, and then indulge in a game of golf, although we do not actually see the midnight sun. If the tourist be a fisherman he can indulge his hobby all day with the certainty of good sport in the many lochs and voes that abound all over the isles. The hotels are good, and the Shetland Isles are easily reached by regular steamboat services from Aberdeen.

### Motor Cycle and Canoe in the Shetlands.—

To finish this article, I would like to relate one experience of my own last winter that may serve to illustrate the dangers of cycling anywhere in hilly country when the ground is covered with ice. I left the town of Lerwick for a trip of about forty miles to the north end of the mainland with a lady passenger in the sidecar. All went well until, breasting the top of a steep hill at speed, I was alarmed to see the down grade in front of me one sheet of glittering ice! I shut off the engine and applied the brakes,

but was too late to stop, and we started to slide down the hill, gathering way as we went. I tried to steer for the ditch, but it was useless, as the whole outfit gradually turned sideways, then stern first. I was hanging on, and praying for a soft spot, when we dashed into a ditch, and for one hair-raising moment the sidecar wheel lifted and hung in the air, while I hung over a steep incline which ended in a rocky burn; then we dropped back right side up. I walked the rest of that hill, returned straight home at a very steady speed, and stopped there until a thaw took place!

ROBERT WILLIAMSON.

The "real" canoe sidecar. Observe the floats and paddle, also the hand-propelling mechanism.

## AT THE CLUB HOUSE.

### A Question of Average Speed.

OUR club notice board appears the following: *Problem.*—A motor cyclist completes one half of a journey at 20 m.p.h. and the remaining half at 30 m.p.h. What is his average speed for the full journey?

Somebody has written in answer, "Smithkins knows," and this is the story.

Smithkins came in blinking his eyes. He had just made the journey to town and back—a stiff day's riding.

"When I get all these flies out," said he, rubbing his face with a handkerchief, "I'll have two or three truckloads sent on to the Hun-Kadaverer-what's-its factory."

"What sort of a run had you?" asked Biffles.

"Not bad," answered Smithkins. "Only averaged 20 m.p.h. going out, what with one stoppage and another; but, coming back, I averaged 30 m.p.h. all right, and, let me tell you, it's not bad, taking into consideration the present state of the roads, to average 25 m.p.h. out and return on a lightweight."

"No; it is not bad," said Biffles. "But you did not average so much out and return."

"I tell you . . . averaged 30 m.p.h. back . . . 20 m.p.h. out . . . and if that's not averaging 25 m.p.h. . . . I will eat my—" (here he mentioned an article of apparel often worn by men).

"I hope you have a good meal," said Biffles, smiling, and then—"Well, I'm off. So long"; but,

half turning round as he reached the door, he added, "By the way, don't think I'm deprecating your to-day's performance—only disputing your arithmetic."

Just then, Dibbs, who had been repairing the flapper perch of his 2 h.p. Overplus, wandered in.

"What's the row?" he enquired. Smithkins opened out and gave it him full throttle.

"Well," said Dibbs, "I don't know what the trouble is, whether it's in the magneto, or the sparking plug, or the design of the exhaust valve cam." He paused in his speech, being occupied in dodging a repair outfit and its flying contents. "But if Biffles says you are wrong there must be something in it."

### A Case of Obsession.

Smithkins (who is on munitions) was late at work next day. For the remainder of the week he wore a far-away look and was very absent-minded. When you asked him for a match he put his hand in his pocket and gave you his pipe. Later he parted with his cigarette case and tobacco pouch in the same way.

About 11.30 on Saturday night the clubroom door suddenly burst open and Smithkins tumbled into the room. "I know" (in real life he would have said Eureka!), he gasped. "Twenty-four"—and then collapsed.

We covered him gently with an old rug from Biffles's sidecar, and shortly afterwards he fell into a deep slumber. A moist and healthy perspiration settled on his brow. We knew the crisis was past. ENGRO.

# MECHANICS FOR THE MOTOR CYCLIST.

## Third Instalment: INERTIA.

Previous instalments appeared on  
July 19th and August 9th.

It is hardly necessary to point out to thinking motor cyclists the great desirability of a little mathematical knowledge—so many questions may crop up, as, for instance, the horse power required to mount a certain hill, the tension of a belt or chain when driving a heavy machine, or the calculation of a gear, that the man who is entirely ignorant of these matters must often be at a loss. In this and the following articles (of which there will be several) the author proposes to discuss some of the simpler problems dealing with speed, acceleration, force, inertia, centrifugal force, etc., and their practical application to everyday questions in a popular manner without unnecessary technicalities. No motor cyclist, therefore, need pass by these articles under the impression that they are beyond his understanding, for everything is explained in simple language.

**INERTIA.**—When a force, acting on a body, produces acceleration the law of action and reaction still holds good, but in such cases the term “inertia force” is given to the reaction. Inertia force may be defined as the resistance that a body offers, to any change in its motion. This resistance is equal in magnitude and opposite in direction to the accelerating or retarding force.

Our tube railways give every facility for the experimental study of the laws of inertia, particularly if the student is prepared to subordinate his comfort to the cause of science by travelling as a strap hanger. To avoid any possibility of misunderstanding, let me explain that it is not suggested that inertia plays any part in the management of these concerns; nor, on the other hand, do I desire to enter into competition with the gentleman whose alluring posters advertising the advantages of underground travel form such a feature of Tube stations. In short, I wish to put forward the “usual disclaimer.” Without pausing to consider the numerous interesting problems in dynamics presented by the lift or the escalator, we will assume the seeker after knowledge to have secured standing room in a Tube carriage. The question of human inertia, as exemplified by those slow-thoughted travellers who call forth the conductor’s appeal to “pass farther down the car, please,” fascinating though it is, must also be passed by.

When the train starts our experimenter will find himself subjected to a force acting in the opposite direction to the direction of motion, of sufficient magnitude to send him staggering backwards down the car were it not for his firm grip of the hanging strap. Observe that there can be no possible doubt—no probable, possible shadow of doubt—about the existence of this force; its effect is just as undeniable as if the subject were pulled violently backwards by some human agency. The stoppage of the train is marked by similar phenomena, except that this force whose effects we are studying

now has a tendency to propel the passengers in a forward direction.

Let us see how these facts square with the definition of inertia force already given. During the acceleration of the train it is, of course, necessary that every passenger in the train must also be accelerated. To impress this acceleration on the passengers force is required. In the case of a strap hanger, the only available means of transmitting this force to him are the friction of his feet on the floor of the carriage and the pull of the strap. This applied force—the “action”—calls into play an equal and opposite reaction which we have spoken of as the force of inertia. The tendency of the passengers to lurch forward on the train coming to rest is explicable on similar lines.

There are, however, other occasions beside the starting and stopping of the train which tend to disturb the travellers’ equilibrium. When a curve is traversed a force manifests itself, impelling them to the right or left of the car. Except that this force acts transversely, instead of in a fore-and-aft direction, its nature is identical with that of the inertia force just discussed. We are therefore led to the somewhat puzzling conclusion that, although the train does not alter its speed, it yet undergoes acceleration. It is at this point that the full significance is revealed of the concluding words

of the definition quoted in the preceding article: “Force is that which changes or tends to change a body’s state of rest or of uniform motion in a straight line.” Now you can change a body’s state of uniform motion in a straight line in two ways. Either you can make the body move faster or slower while still maintaining the same direction; or the body can be diverted from a straight into a curved path, no alteration being made to the linear speed. Force is required to effect either of these changes. In the first case, linear acceleration is the result; in the second, what is known as *radial acceleration* is brought about. Any object travelling in a curved path is subjected to this radial acceleration,

When a wheel is revolving at a uniform speed every point on it has an acceleration to the centre, as is shown in the above diagram.

### Mechanics for the Motor Cyclist.—

which always acts towards the centre of the circle along which the object is moving.

Thus, the direction of the acceleration of a body traversing a circular path is as shown by the arrow in the figure. The existence of the force necessary to impart this acceleration can be proved easily enough. If a stone attached to a string be swung round in a circular path, it is common knowledge that a constant inward pull must be exerted on the string.

In exactly the same manner that an object does not suffer its linear speed to be changed without an effort, so the object resists any tendency to force it from its straight path. In the one case, we have termed this resistance or reaction the "inertia force"; in the other case, although the reaction is just as indisputably an inertia force, we give it the distinguishing title of *centrifugal force*. So numerous are the ways in which

this force affects the motor cyclist that a separate article is necessary for its adequate consideration.

It may, however, be permitted at this stage to moralise a little on the behaviour of animate matter when undergoing changes of motion. Those readers who find that they, too, offer great resistance to anything that disturbs or tends to disturb their state of rest—who are, in brief, what an unfeeling and unscientific world calls lethargic, or even lazy—can draw consolation from the knowledge that, after all, they are only acting in accordance with the immutable laws of Nature. But I fear that the value of this reflection will be entirely nullified by the fact that it will never meet the eyes of those who might benefit by it; for, quite apart from the inherent improbability of there being any indolent readers of *The Motor Cycle*, the inertia of such rare specimens as may exist would effectually prevent their studying articles of this kind.

(To be continued.)

## THE TRIUMPH GEAR BOX.

### A RECENTLY PATENTED METHOD OF OPERATION.

THE accompanying sectional drawing shows a system recently patented by the Triumph Cycle Co., Ltd., whereby the gears are shifted by means of spring controls, so that a movement of the lever from one position to another need not necessarily mean a simultaneous movement of the gears. As every rider knows, it is detrimental to the internal mechanism of a gear box to change from one gear to another when the gears are under load, but, on the other hand, it is an advantage to be able to shift the gear lever from one position to the next in the knowledge that the change will not take place till the load is momentarily released, when (by a movement of the exhaust control or the throttle) the dog clutches slide automatically into place—perhaps some seconds after the movement of the lever.

Such foolproof mechanisms for gear changing are already widely used, and, apart from the spring-striking gear reducing the likelihood of mishap in the hands of an uninitiated rider, add much to the convenience of control from the point of view of the expert.

The accompanying drawing, which is a front elevation partly in section with the front of the casing removed, requires some explanation.

The drawing is made purely to show the actuating mechanism, it being taken that one is looking on to the end of the shaft mounting the change-speed lever. The movement of the gear lever rotates the cam, which is mounted on the same spindle as the lever. It will be observed that this cam contains two plungers, held outwards by a spring housed between them. It will further be observed that holes are cut in the

cylinder in which the cam is carried to receive the ends of the plungers as the cam is rotated from one gear position to another, thereby acting as resilient stops for the various gear positions. These four holes, then, represent respectively the first speed, neutral, second, and top.

The upright arm strikes the dogs from one position to another by rocking either to left or right on the spindle mounting the cam, and this motion is imparted to it by the motion of the cam through the spring plunger contained in the arm and bearing upon the face of the cam. As shown in the drawing, it can be taken that the gear lever has been shifted from second speed to first speed, but the gears being under load have resisted the movement; therefore the spring plunger has been compressed upwards, the arm remaining stationary. Immediately the gears cease to yield resistance, however, the pressure of the spring will cause the plunger to ride down the face of the cam into the groove, automatically swinging the arm into first gear position. On the underside of the cam a stop is shown, the sole object of which is to prevent the cam turning too far in either direction.

One advantage this mechanism immediately suggests is that the gear "quadrant" is contained in the gear box, and thereby sheltered from grit and shielded from damage. The patented operating mechanism is certainly ingenious, and the gear box should present a clean exterior, there being no outside fittings exposed to wear and requiring lubrication—this latter point being an important one as regards external cleanliness.

Front elevation showing the control system employed in a gear box recently patented by the Triumph Co.

## MILITARY NOTES.

## A Further Selection of Photographs and Letters from Young D.R.'s.

## RECRUITING.

THE railway companies and the police have, we are informed, supplied their full quota to the 500,000 men asked for by the War Office by the end of July.

## 15 YEARS 10 MONTHS ON ENLISTMENT.

"I SAW in a recent issue of *The Motor Cycle* a query asking who was the youngest despatch rider to go on foreign service. Well, I think I go near claiming that honour.

"I enlisted on September 24th, 1915. I was with the Expeditionary Force in France from January 16th, 1916, until July 27th, 1916; then discharged on July 28th, 1916. From the day of joining to landing in France I was riding on Salisbury Plain and in the South of England. I spent a winter on the Plain and one in France, and was in three squadrons of the R.F.C. I had three new P. and M.'s in that time, two of them breaking under the head lug through sidecar work. I also received instructions at P. and M.'s on their machines.

"If you require any more particulars I will be very pleased to send them.

"I was born on March 11th, 1900, and am now 17 years 4 months.

"W. GILLINGHAM."

## CPL. E. APPLEBY SEES FOREIGN SERVICE AT 18 YEARS 4 MONTHS.

"I ALWAYS send my son out every week a copy of *The Motor Cycle*.

I happened just to look at it, and was surprised to see on page 85 the photograph and name of 'the youngest despatch rider.'

"May I mention that I think my son must be among the youngest D.R.'s, as he went to France at the end of July, 1916, and was only 18 in

the previous March, making him 13 years 4 months, and he has not been home since.

"ANNIE APPLEBY."

## A GOOD RECORD.

"ON reading over your paper I see a reader wishes to know if there has been a younger D.R. on foreign service than his son, William Roughley.

"My brother, John Barclay Chalmers, joined the R.E. as D.R. on the 1st July, 1915, when 17½ years old, went to France 21st August same year, and was at the battle of Loos. He was not 18 till the middle of November. He has been kept at it all along, and been only once home (May, 1916), so I think this is younger than W. Roughley, and likely there may be even younger ones out. "R. H. CHALMERS."

Cpl. J. B. Chalmers,  
R.E. (Signals).

## JOINED AT 16 YEARS 10 MONTHS.

"I READ with much interest the letter from a Rochdale reader which spoke of the youngest despatch rider on foreign service. Personally, I know of three, of whom I am the youngest, that can beat his record. I joined my present unit in France at the age of 16 years 10 months, and have since seen twenty-eight months' service under all sorts of conditions.

"I may also state I have never missed an issue of the 'Blue 'Un' since my arrival out here, and the boys are always anxious to borrow it.

"Wishing the paper every success,

"W. E. COOK,  
Cpl. R.E."

## AWARDED THE RUSSIAN CROSS OF ST. GEORGE.

MR. R. MOSELEY, of Walthamstow, sends us the following interesting information about his brother, who joined the M.M.G. when he was 16½ years old:

"I would inform you that my brother, Gunner K. Moseley, M.G.C., late M.M.G., whilst on active service in East Africa,

gained the Russian Cross of St. George. He writes regarding this as follows: 'You will be pleased to hear that I have been awarded the Russian Cross of St. George. The armoured motor cars went into action on August 17th, 1916, on a river named the Wami (East Africa), when they were signalled to retire. They could not see the signal, so I went and brought them out.'

"These are all the particulars I have of this deed, but I can give you a brief account of my brother's Army life.

"He joined the M.M.G. as a gunner in June, 1915, when he was 16½ years of age. About the November of that year he was promoted to bombardier, but gave up his stripe when he transferred to the 5th L.A.M. Battery in February, 1916, and sailed for East Africa. He was there until quite recently, when he was shifted to Egypt to recuperate after the hardships and fevers of the East African campaign. He is there now waiting to take up a commission in the R.F.C.

"I am sorry to say I have no photograph of my brother other than in a group of the 5th L.A.M.B., published in your issue of 24th February, 1916."

## A HARDENED CAMPAIGNER AT 17 YEARS 4 MONTHS.

"WITH reference to Mr. Roughley's short paragraph in your number dated July 19th, raising the interesting question as to who is the youngest despatch rider, I should like to mention that I enlisted as a despatch rider at the age of 14 years 10 months. I have already served with the Overseas Forces in France, Egypt, and Macedonia.

Cpl. F. H. Chadwell

"My present age is 17 years 4 months, having served in all sixteen months abroad. I was eventually claimed home by my parents.

"I should like to know if there is any despatch rider who can claim to be younger than this.

"Wishing your paper every success,  
"F. H. CHADWELL."

Cpl. E. Appleby. The mud-covered motor cycle will give an idea of the road conditions encountered.

## ROYAL FLYING CORPS P. & M.

**W**E have from time to time alluded *en passant* to the various improvements that have been made in P. and M. motor cycles since the day—now seeming far distant—when the factory was handed over to the Government. Since then the private owner has contemplated the latest products of the factory from afar, and even the most patriotic supporters of the make, and there are many in the North—men who have ridden P. and M.'s since the very earliest days of the pastime, who have ridden nothing else, and who, perhaps, with the characteristic conservatism of the Celt, never intend to ride anything else—have been compelled to hold on to their old machines since 1914, or thereabouts, whilst the R.F.C. consumed the new.

### As a Double Purpose Mount.

P. and M. motor cycles are perhaps most remarkable for their unfailing reliability and for their wearing properties. There are few machines which, as an individual make, have been so much abused. The P. and M. was one of the first machines to figure as specially adapted to sidecar use—the chain drive and two-speed gear accounting for this. Anyone who possessed a P. and M. regarded it almost as a sacred duty to attach a sidecar to it, with the result that it developed along the lines of a machine specially fitted to meet the privations and hardships of life.

The wearing quality—that is, its long life as an absolute reliability mount—of the P. and M. is doubtless due to the very wide margin of efficiency, both as regards strength and wearing surfaces, of the machine throughout. The engine parts are massive, ground and finished to a very high standard of workmanship. While visiting the P. and M. factory we have, on many occasions, been struck by the thoroughness and minute care brought to bear on even the smallest and apparently most insignificant portions of the machine. Not a single point is scamped, and it is this combination of fine machining, good material, ample strength, and minute detail care which is at the root of P. and M. reliability and which accounts largely for its wearing qualities.

Transmission side. Note the strengthened front mud-guard stays and the spring fork and chain case alterations.

tain ascents, watersplashes, and so on, it has naturally partaken of those features which render a machine well adapted to such conditions. But it must not be imagined that "plugging along with a sidecar" is the sole purpose of the P. and M. Up to 1914 these machines could "hardly be described as antelopes of the road," as one writer has already put it, but 1914 saw an immense improvement in the speed of the P. and M. To-day the machines handed over to the Government are capable not only of "doing" 45 m.p.h., but of holding that speed for a considerable period, and this in delivery tune. We know from our own practical experience that on long journeys the P. and M. of to-day is certainly among the fastest of British machines of the single-cylinder touring type.

### Recent Alterations.

The chief alterations that have been made to the P. and M. since last we fully described it are mainly of the detail order, though none the less interesting and important. Every part of the machine which has been found to be lacking in strength during the strenuous trial of warfare has been strengthened or redesigned. This may sound a small matter, but let not the reader be deceived.

In pre-war days this machine was renowned for its solidity and strength of design, yet in the hands of the military the original peace-time model was found to be sorely lacking in strength. The most unexpected members fractured under the continuous strain, and various revisions and additions were found necessary during the early months of the war.

As regards the general lay-out of the machine no

Part sectional view of the two-speed gear: one of the split wedge bars and rollers *in situ*. Inset is the operating sprocket, showing internal thread and push rod.

**Royal Flying Corps P. & M.—**

radical alterations have been made, but the new gear and the fresh points of design in the spring fork mechanism are certainly worthy of comment.

**Gear Improvements.**

Having had considerable experience with the new gear, we are able to discuss it with some freedom. One of the most marked improvements from the point of view of the practical rider is the adjustable wedge bars. With the old type of gear the wedge bars required renewing every 5-6,000 miles owing to the wear of the friction faces of the expanding phosphor-bronze rings. The renewal necessitated taking the gear entirely adrift—a task which many amateurs shied at—and sending to the makers for bars of the next gauge, a matter usually of some delay and inevitably of some nuisance. In the new gear all this trouble is done away with by the simple expedient of splitting the bars lengthwise, so that they can be thickened by inserting thin blades of steel down their centres, thus taking up the wear. These packing pieces are supplied in different gauges by the makers, and can be inserted with a pair of pliers after removing the small bolt which operates the wedge bar, the gear being placed in the neutral position during the operation.

Care should be taken, however, not to insert the packing pieces till the wear is shown to be considerable by excessive movement of the lever, for if the wedge bars be too thick this will cause both gears to bind at the same time. The mechanism then heats up to an extent which is likely to burn up the lubricant, and may thereby cause considerable damage. It should be noted, after inserting the packing piece, that the engine is quite free, and that there is some movement of the lever in the central position.

**Gear Lubrication.**

In the new gear the expanding rings are in two half circles, each ring being expanded by two wedge bars, and the friction surfaces of the rings are provided with diagonal oil grooves into which the oil is squeezed on the engagement of the gear. The rings are also larger than the original type, and on account of these revisions not only is the "take off" of the gear much smoother than of yore, its sweetness of engagement, and all-round efficiency added to, but its gripping qualities are no longer affected by the lubricant used. Those whose experience of P. and M. gears dates back some years will recall that the old pattern were apt to slip, if oil instead of grease were used; but in the new gear ordinary engine oil is the only lubricant required. A small brass force pump is—or should be—supplied with the machine, and by means of this a charge of oil is drawn from the tank supply and injected straight into the gear every 3-400 miles.

The lubricator consists of a small red elbow, protruding ostentatiously before the rider when the

gear case cap is removed from the chain case. This elbow receives the spout of the oil pump, and it contains a non-return valve, which prevents the oil being slung out by centrifugal force.

Though this way of oiling is easy and efficient, we have not found it to be very permanent, and we obtained better all-round results by screwing the non-return valve from the elbow and injecting vaseline by means of a pump having a screw-down plunger. The heat of the gear proved quite sufficient to keep the vaseline in an adequately liquid state.

**Spring Fork Revisions.**

The improvement of the spring forks is proportionately noteworthy. The old pattern, in which semi-circular plated members adjoined the wheel spindle and moved with a circular motion through the bridges embracing them, was prone to wear at sundry different points, and it was a matter of opinion whether or not the sliding plated members should be kept dry or lubricated. If lubricated they collected grit, which formed itself into a grinding paste, while if kept dry wear was still inevitable, as they formed a convenient lodging place for road slush, etc. In the new forks links are used in place of the semi-circular members, and screw-down grease cups of sensible size are fitted, so that grit is forced out of the large bearing surfaces by the act of screwing down the lubricators.

The present spring forks have few wearing parts, and the bearings are provided with large grease cups.

The detail improvements that have been brought into practice since the outbreak of war are numerous. The back wheel external contracting brake is strengthened and its efficiency increased. Originally the closing motion of the band was effected by the pull on one end only; now, by means of a bell crank arrangement, the band is tightened at both ends, ensuring an increased gripping surface and longer life for the lining. The band is, moreover, mounted in such a way that it cannot wander from its proper position.

The lamp-bracket is mounted on an extension of the main fork guides, and the back of the saddle pan is given an upward curve so that, with a heavy rider, it cannot bump the rear wheel mudguard. We are surprised to find that the original pattern front wheel mudguard has been retained, though it has been much strengthened as regards attachment.

**The Twin-cylinder P. and M.**

The P. and M. twin is, of course, gradually developing, though naturally circumstances do not permit any expenditure of labour upon it. This model, we are informed, with its four-speed gear and 90° engine, is to be the sidecar machine of the post-war catalogue, the two-speed single-cylinder model being the solo mount. Many, however, will probably regard the twin-cylinder model as an ideal solo mount, for it is not particularly heavy, while with its simple four-speed gear a very high top gear ratio could be utilised for solo riding. Both models are to be considerably altered as regards detail fittings.

## SPECIAL FEATURES

## Second-hand Prices in France.

In France second-hand British-made motor cycles are fetching astonishing prices. One reader solemnly informs us of a four year old Rudge which fetched the equivalent to £96. Rather tall!

## A Missing Tube.

A reader asks us if we will gently request the rider of a Scott sidecar outfit, who was hung up between Newmarket and Barton Mills from 2.30 to 7 p.m. on Sunday, July 22nd, kindly to return to the stranger who took pity on him "the inner tube which enabled him to get home."

## A J.A.P. Enthusiast.

A garage proprietor was charged at Wood Green last week with feloniously stealing and receiving between February 1st and August 16th three engine cylinders, five pistons, 270 phosphor bronze bushes, fourteen valve caps, nineteen valves, eighteen cam levers, fifty-five piston rings, and other motor cycle engine parts, together value £69 10s., belonging to J. A. Prestwich, Ltd., Tottenham.

Although the majority of light-weight motor cycle manufacturers and ourselves strongly discourage attaching sidecars to this type of machine, the photograph shows the strenuous work lightweights occasionally perform, for Capt B S. Millard, R.E., and his passenger, Lt. H. J. Ingman, together weigh 30½ stones. The outfit is a 2½ h.p. Enfield.

## Is Pillion Riding Dangerous?

In pillion riding the chief risk lies in the fact that, if a smash *does* occur, two persons are involved instead of one, and the rider of the machine cannot help but feel himself responsible for his passenger. Further, the likelihood of risk is increased, for it is impossible to make so rapid a swerve to avoid mishap as when riding solo. A lady passenger, sitting sideways on the carrier, is not in a position to assist the rider or save herself in the case of side-slip, and therefore the practice of carrying a lady is more risky than that of carrying a man.

## Description of Stolen Machine.

The following is a description of the Matchless (Model 8B) motor cycle and sidecar stolen about midnight on August 14th from the Matchless works—Collier and Sons: Engine No., 34,572; frame No., C3,041; Hutchinson 750×75 mm. tyre on rear wheel and 650×75 mm. of the same make on sidecar wheel; Palmer Cord 650×65 mm. front wheel. It is a three-speed countershaft gear model, with silent chain drive; Lucas lamps, generator, and horn are fitted; also Stewart speedometer and hand warning horn fixed on front of sidecar body. A crack in the frame will shortly necessitate repair, and the sidecar mudguard and back mudguard are both damaged. There was a No. 2 Brownie camera and several spares in the sidecar body, and the outfit is enamelled Matchless grey, with green panel on tank.

## Average Prices.

We give below the prices of second hand machines offered for sale in the last issue of *The Motor Cycle* and in the adjoining column the average prices based upon the latest figures available. Thus the general trend of the market is visible at a glance though in the first column many blanks inevitably occur. This is due to an insufficient number of one model on which to base an average, or to the lack of essential particulars in the advertisements, many advertisers making the fatal error of omitting the date of manufacture. The word "combination" indicates a sidecar outfit as supplied by the makers, while "sidecar" implies that the fitting has been carried out by the owner.

HEAVY WORK FOR  
A TWO-STROKE.

**The National War Funds.**

At the week-end the principal war funds stood as follow:

The National Relief Fund (distributed £3,641,622) .. ..	£6,220,190	0	0
British Red Cross Fund .. ..	7,217,014	1	1
Tobacco Fund .. ..	135,594	0	0

**"The Motor Cycle" Index.**

We are requested by our publishers to announce that the index to *The Motor Cycle* for the six months ended June 30th, 1917, is now ready. Copies, price 3d. each, post free, may be obtained from the publishing offices of *The Motor Cycle*, 20, Tudor Street, London, E.C.4.

**Home-produced Petroleum.**

The Petroleum Bill, published during the week-end, gives the Government the sole right for getting petroleum in the United Kingdom. Any person obtaining petroleum without a licence would forfeit three times the value of the petroleum obtained. Parliament will pay for petroleum obtained on behalf of the Crown to a Special Petroleum Royalties Fund, and holders of licences will contribute £9 per ton. The Board of Trade may search for and get petroleum and grant licences.

It is a well-known fact that petroleum is obtainable in various parts of the United Kingdom, there being oilfields which have actually produced petrol for some years between Edinburgh and Glasgow, while in the west part of Norfolk there are also said to be other sources of petroleum. Unfortunately, these oilfields will not be permitted to produce any petrol for private purposes.

**British Imports and Exports for July.**

The importation of complete motor cycles has ceased completely, and a gradual reduction is taking place in the value of the parts and accessories which reach this country, this month's returns being reduced by £629 compared with June figures.

**IMPORTS FOR JULY.**

	1915	1916	1917
Number of motor cycles	495	253	—
Value of motor cycles, parts, tyres, accessories	£37,827	£27,234	£1,585

**BRITISH EXPORTS FOR JULY.**

There is a slight reduction as against June figures, but their value is well ahead of the July figures for 1915 and 1916.

	1915	1916	1917
Number of motor cycles	881	866	661
Value of motor cycles, parts, tyres, accessories	£64,601	£71,855	£73,437

**PETROL FIGURES.**

Number of gallons imported in July:

1915	1916	1917
15,458,600	11,526,000	12,346,846

The number of gallons imported during the seven months of this year was:

January .. ..	13,001,740
February .. ..	12,257,984
March .. ..	9,246,546
April .. ..	10,258,951
May .. ..	12,270,934
June .. ..	11,327,434
July .. ..	12,346,846

It will be noticed that close upon 1,000,000 gallons more were imported last month than in June.

**Petrol for Cigarette Lighters.**

Last week two motor cyclists were standing by their machines, when a well-dressed man came up to them and asked if they would kindly fill a big cigarette lighter. Is this the latest dodge for obtaining petrol on which to run one's Auto-wheel?

**Water in the Petrol Tank.**

A D.R. in the Royal Flying Corps informs us that when he was last on leave he had an arrangement with the garage proprietor that when he asked for paraffin he meant petrol. This being a blind for the benefit of other would-be purchasers, who at the time happened to be in the garage, he suggests that this might explain the water in petrol tank mystery.

**New Tyre Repairing Works.**

Messrs. Harvey Frost and Co. have now centralised their tyre repairing workshops, and the departments at Great Eastern Street and Charing Cross Road have been transferred to their new premises in Great Portland Street.

FROM SCRAP HEAP TO COMPLETE MOTOR CYCLE (see next page).

# FROM SCRAP HEAP TO COMPLETE MOTOR CYCLE.

How War-time Wrecks are Rejuvenated.

**N**OT many weeks ago one of our correspondents called our attention to a vast collection of derelict motor cycles, unprotected from the weather, and to all intents and purposes useless scrap, which was to be found in a field near a certain railway in the Metropolitan area. There were many wild speculations as to the ultimate fate of these poor wrecks. A rumour was started, and spread like wildfire, that they would be sold by auction, and words to that effect actually appeared in print (not in *The Motor Cycle*, we are glad to say), with the result that the unfortunate O.C. responsible for them was bombarded with letters and even visits from bargain-hunters. The outcome of all this was a tour round the depot and the interesting article and photographs which appeared in the issue of June 14th. Next we published a brief description of the depot to which all the new machines and those which have

A group of A.S.C. testers ascending the hill.

sent straight from the collecting depot to another, which is a well-organised motor cycle repair shop. It is as well to point out that when the machines arrive, mostly from abroad, they are in such an appalling condition that a few days or weeks more exposure can make little difference to them. Even if they were stood in the most luxurious sheds the process of oxidation would go on just the same, but now, possibly through the remarks concerning them which have appeared in the press, they are covered up with tarpaulins as a protection from the elements.

Our first article dealt with the terrible problems these bent, battered, and war-worn relics offered to the repairers, but the A.S.C. mechanics are skilled men, and the department, which is a building of considerable size, though barely large enough, is capable of turning out sixty finished machines a week. Nearly everything is done under one roof, but the side-car body building (who would have thought three

The engine repair shop

been repaired are sent and thence distributed to the various units, while now we propose to terminate the series by an account of the manner in which the machines are salvaged from the cauldron of war and made fit to serve their country again.

It will be seen from this account that in one branch of the Army at least business methods are employed, and there is no wastage. This hopeless tangle of machines is sorted out and

The frame shop where the machines are stripped and assembled and the frames repaired. The congested condition of the shop is clearly noticeable.

**From Scrap Heap to Complete Motor Cycle.—**

years ago that the Army would build its own sidecar bodies?) is carried out at another depot. The officer in charge is a keen motor cyclist and rides a  $3\frac{1}{2}$  h.p. twin James, and by the way we saw him threading his way through the traffic the other day we should say he is a driver of no mean skill.

This officer first took us to the stripping and erecting shop. At the moment both these operations are carried out under one roof, but they will shortly be separated. All the machines are placed on high benches, forty in number, so that the men can work at them comfortably. We noticed a Scott completely stripped, and a little further on a Triumph absolutely complete. It was hardly distinguishable from new, being stove-enamelled, while even the cylinder was blacked. Its fine condition marked it for work abroad, as those machines which are not quite in such good order are "for home service only." Near by was an ancient Zenith, also in process of renovation. Next we saw stacks of frames, repaired but waiting for engines and gear boxes, and among them, quite a curiosity in an Army repair depot, a Lea-Francis. Close by stood a row of machines which had been previously overhauled ready for testing. This depot has its staff of testers, and even its own test hill, of which more later. A little further on stood a row of motor bicycles which had been tested, but lay awaiting final adjustment before being sent away.

**Extending Use of the Military Sidecar.**

Our readers will remember the numerous Scott machine-gun outfits which appeared shortly after the war began, but few will realise that the buzzing Scotts one sees about London fitted with sidecars carrying coffin-like boxes are these identical machines. It is, nevertheless, a fact, and this depot makes a speciality of the conversion, and here are carried out the alteration of the frames and the building of the bodies. Not only are these frames fitted to Scott machines, but to other makes as well, and it is interesting to note that all the more powerful machines fitted with change-speed gears are now being equipped with sidecars.

In the A.S.C. Repair Depot nothing is wasted. In one group battered lamps are made like new, inflators which are damaged are similarly treated, while the Scott radiators are sent to the car repair department, and are there mended and tested under an air pressure of 10 lb. per square inch while the radiator is immersed in water, so that any sign of a leak is shown by bubbles. Skilled instrument makers see to the speedometers, and in one of the repair shops all types of magnetos are dealt with.

Our next visit was to the engine repair shop, one of the supervisors of which is Cpl. W. F. Newsome, the well-known Triumph rider. It was quite like old times to meet him again, and though he is just in his

element, he told us that he would be glad to be riding in competitions once more. His former partner, R. R. Fletcher, joined the Public Schools Battalion at the beginning of the war, got a commission in the South Lancashires, and the last he heard of him was that he had been wounded in the neck in Mesopotamia.

**More Well-known Competition Riders.**

As regards the repair of engines, Newsome told us that there was an excellent system of checking in the department. When an engine is received, a corporal looks it over and details the repairs necessary and what new parts are required. If, for example, a crank case oil lug is broken, a new part is obtained and fitted, so as to save time, but the breakage is acetylene welded, so that it is finished and ready for the next machine of that make needing a similar repair. Splendid work was turned out by the men. Some did not know much when they arrived, but they soon learned and became skilful craftsmen. Men had been recruited from well-known firms in the trade — from Wauchopes, Maudes' Motor Mart, and various leading factories. The Staff-Sergeant was Jepson from Zeniths, who had raced at Brooklands; there was Oliphant, the well-known Premier rider, a tester; De la Hay, brother of the famous Sunbeam exponent; and Heath, another Sunbeam rider.

Many curious repairs have been effected. Some makers engaged on special Government work can supply no spares at all, not even to the Army, and it has been discovered that a New Hudson cylinder will fit a Premier, so such methods are followed to keep the home service machines in running order.

The next shop we went over was devoted entirely to gear box repairs, mostly carried out by mechanics from such firms as Sturmev-Archer, Ltd. One of the most interesting machines we saw in the shops was an ingenious air compressor made out of two 7 h.p. Indian engines placed side by side and

The air compressor made out of two 7 h.p. Indian engines.

with their main shafts coupled up. The exhaust valves were rendered automatic, and the air was drawn in through these and pushed out through special valves. A sleeve was inserted under each detachable head so as to increase the compression space, and longer holding-down bolts were employed. The two engines were so arranged that when the pistons in one were at the bottom of the stroke, those in the other were at the top. This compressor works six forges, and is so successful that another was being made like it at the time of our visit.

In another part of the building are a number of small rooms, each one of which contains the spares of one particular make. The largest stock belonged to Triumph machines, next came the Douglasses, 234 and 4 h.p., then Rudge, and so on. Makes of which comparatively few are used in the Army shared a room

### From Scrap Heap to Complete Motor Cycle.—

with others. There was also a general store for material, tools, etc. (no man can receive a new tool unless he produces the old one), and an equipment store, whence tool kits, lamps, pumps, horns, and other accessories were issued. Machines for use abroad are given new accessories, while those employed at home are equipped with those fittings which have been repaired in the other depot. Beneath the building is a cool cellar in which tyres and tubes are stored.

### The Official Test Hill.

There was one point which struck us very forcibly in the course of our visit to the works, and that was the fact that the shops seemed unnecessarily crowded. It is evident that the work has increased to such an extent that it could be done better in much larger premises. Altogether 250 hands are employed.

This article, we think, will convey to the average reader a good deal which is novel to him, and he will feel comforted to realise that in some departments of the Army efficiency is the order of the day, while waste is not only discountenanced but is actually non-existent.

Having concluded our visit to the repair works, we were next taken to the A.S.C. official test hill, which is situated in the south-east of London. Here we found a group of testers, each wearing a yellow armlet on which

was the letter "T" in black, and among them we noticed the well-known competition rider, J. Oliphant, formerly with the Premier Cycle Co.

### A Rejuvenated Scott.

The hill is of considerable length, and has a maximum gradient of 1 in 8. All the machines were well tuned and made no bones about the climb. One interesting incident which we may mention was an unofficial trial carried out by four testers on one 4 h.p. Triumph (1 h.p. per man). Although so abnormally loaded that the back tyre was almost flat, the machine made a magnificent ascent. Among a group of motor cyclists who ascended the hill was the officer in charge of the repair works, driving a Scott sidecar combination. This was one of the old machine gun outfits which had seen service abroad. It had been done up in the repair works, and was pulling magnificently. After witnessing the demonstrations up the test hill we journeyed back to town in it. The machine ran with wonderful smoothness, and ascended Dog Kennel Hill on the way back on top gear at a remarkably good pace.

The officer in charge is certainly a most skilful driver, and piloted his machine with considerable address the whole way back. An engineer by profession, he was, for some years before the war, an enthusiastic amateur motor cyclist.

(Left) A Triumph and a Douglas before and after treatment at the repair works. (Right) A selection of motor cycles after being repaired at the depot. The Douglas and Triumph machines illustrated are all labelled "S.H., Overseas." This means to say that they are second-hand machines in good enough condition for Overseas work. (Inset) A group of well-known motor cyclists now in the A.S.C. working at one of their motor cycle repair depots. Reading from left to right: Pte. J. Oliphant (Premier), Cpl. W. F. Newsome (Triumph), Staff-Sgt. H. Jepson (Zenith), Pte. H. Langman (Scott), and Pte. T. Heath (Sunbeam). Oliphant is holding the corps mascot.

## TWO MEN AND A TANK.

**A** REMARKABLE story of a N.C. officer, private and a Tank is told in the list of awards published in the *Gazette*:

Pte. F. Brown (D.C.M.), accompanying an N.C.O., followed a Tank to its attack upon a hostile battery, keeping close behind. The Tank having fired a broadside the two men charged the position and captured a gun and its team. They then proceeded to attack another gunpit, when the N.C.O. was knocked senseless by a bomb. Pte. Brown

then carried on by himself and captured the gun team single-handed. He then attempted to mount a wounded horse and do further good work, but was unable to manage it, so returned to his company, whither the N.C.O. shortly followed him.

The non-com. was Cpl. H. Carter, and the official account stated that when he recovered consciousness he found that his companion had captured the team. "The dash and determination of these two men," it is stated, "were nothing short of marvellous."

## D.R.'S AND THEIR WORK.

(IN FOUR INSTALMENTS)

### PART III.—SUPERVISION.

By D.R.

D.R.'s and their machines and their work, and there is no such thing as "joy riding." D.R.'s are never allowed to use their machines for anything except actual official work, and it is almost impossible to get permission to use a motor cycle for one's own personal pleasure. D.R.'s are liable to be halted at any time by the military police and asked to produce some authority for their journey. They have regular set times to be on duty, off duty, or in billets, and these times must be strictly observed. Their machines are inspected thoroughly by men who know their job and who strafe any D.R. whose machine shows any sign of neglect or abuse. Of course, this is all as it should be to prevent waste of money in fuel, wear and tear, etc. But, on the other hand, in other parts a D.R. is practically his own master.

#### Inspection.

It is very necessary that motor bicycles should be inspected frequently to check any unnecessary wear and tear through carelessness, neglect, or abuse. This may be done by the officer in charge of the depot, if, indeed, there is such a person. In many cases motor cycles are stored in mechanical transport depots, and are then inspected periodically, say three or four times a year, by the Inspector of Mechanical Transport. This officer is generally very practical at his work, and makes a very thorough inspection of cars or lorries costing up to £1,000 or more, but he does not always attach much importance to the £50 or £60 motor bicycle. I have on two occasions seen an assistant travelling with the Inspector of Mechanical Transport specially to inspect motor bicycles, but neither of these assistants was exactly expert. This state of affairs is to be regretted, as the work of the inspectors is really important.

#### The Artificer.

This is another man for the wise D.R. to keep in with. He can do just what is expected of him in his capacity or he can do a lot more. He is generally an expert on motor cycles, and can frequently exchange useful "tips" with the more considerate type of D.R. But he is not the man to be "bounced" by the young knut type. If he is decently approached by anyone requiring advice as to how to obtain the best results out of his machine he will freely give the benefit of his experience, which is generally pretty considerable. If, however, the young knut tries to teach an artificer his job the result may be rather disagreeable—for the knut. He may have to wait rather a long time for any small repair to his machine,

and then find that the artificer has done no more than what was actually his job, when he might just as well have done this, that, or the other while he was at it. The artificer, of course, spends most of his time in the workshop, and is generally glad to have an opportunity of "testing" a machine after repairs or an overhaul. The considerate D.R. will not begrudge this little "testing" run, whether it is necessary or not, and, in return, he may find that his spare tube or spare belt or other *running* repairs (which are *not* artificers' work) have been properly attended to, and that all parts have been properly cleaned and oiled, and such little extras as mudshields, handle-bar muffs, etc., fitted.

#### Repairs.

Repairs are of two kinds, viz., running and workshop, and sometimes it is rather hard to draw a line between the two. But usually any repairs that can be carried out on the road by means of tools and spares which are supposed to be carried on the machine are regarded as "running repairs," and should be done by the D.R. Other repairs, which require the use of heavier tools and perhaps greater skill and experience, are really "workshop repairs," and should be done by the artificer. Sometimes, however, a minor breakdown may occur quite near the workshop, when it is more convenient to push the machine a few hundred yards back to the garage than to effect the necessary repair on the roadside. In such a case the artificer can be very obliging when asked, "Would you mind repairing a puncture for me?" But he is not always quite polite when told, "This old 'bus wants a new exhaust valve fitting, and the belt is slipping."

Even in the workshop much patience and ingenuity have to be exercised, owing to the lack of sundry tools or materials, which have been borrowed or lost or never provided at all. It is quite pathetic to hear the remarks of an artificer when sawing through a large nut, using the point of an old scythe because someone has borrowed the workshop hacksaw!

There is frequently great trouble and loss of time in getting the very smallest requirements in the way of necessary small tools, etc. A requisition for a dozen assorted small files, value about 5s., may be returned with a chit asking why these are required. The reply goes back, "Because the old ones are narpooh." This brings a request for a full report from the N.C.O. in charge of the workshop as to how the articles in question had become unserviceable, and intimating that if the aforementioned articles were sent to so-and-so, accompanied by an Army Form No. so-and-so, duly completed, they would be placed before the next board, and, if considered necessary, they would be replaced in due course.

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

#### WHY NOT ACETYLENE?

Sir,—I note with interest an idea put forward by "McAdam," Liverpool, in your issue of August 16th, regarding the utilisation of acetylene gas. A short time ago my petrol gave out when nearing my destination. A friend with me disconnected the tubing from the head lamp and pushed it well into the carburettor inlet. The car—an 8 h.p. Bedelia—ran to a garage, a matter of 300 to 400 yards. This may probably be a freak, but I am sure some of your many readers could relate a like experience.

PEDLAR.

#### BENZOLE AS A MOTOR FUEL.

Sir,—As a constant user and keen advocate of benzole before the war, I was very interested in the article by "L.A.S.," and can fully bear out all his statements regarding its utility as a motor fuel. The principal defect I experienced was the rapidity with which it attacked the tank enamel, and great care had to be taken when filling up unless a demonstration of its qualities as a paint solvent was desired.

The figures giving the comparison with petrol are interesting, but I should like to have the freezing points also. During a particularly cold period one winter I suffered from a frozen-up jet with benzole on two occasions, involving a considerable waste of time before the trouble was traced and remedied. This was the only real advantage I discovered petrol possessed at that time over the home-produced fuel.

F.E.S.

#### PETROL ECONOMY.

Sir,—Some time ago I applied for a permit to purchase petrol at the rate of two gallons per month for three months. In due course I received a reply from the Petrol Control Committee saying that on account of the present shortage they could not allow me this small quantity.

Can you tell me, through your valuable paper, how the proprietors of two well-known Scottish Sunday papers can get a supply of petrol to run motor cars from Aberdeen to Elgin and back *via* the Banffshire coast with their newspapers on a Sunday? I understand they have three cars doing this work for them.

In view of the present shortage, do you consider the carrying of newspapers by motor car on a Sunday an absolute necessity? If petrol can be allowed for work such as this, I do not see why business men cannot get a reasonable supply.

Surely something could be done to ensure that petrol, if granted, be used in work of national importance.

I might add that the route mentioned would be about 200 miles.

DISGUSTED.

Keith.

#### INVERTED CONTROL LEVERS.

Sir,—Capt. Lindsay hardly explains what I wanted to know, but he seems now to come down entirely to the question of the front brake lever being inverted. We will let it go at that. There is, however, a word I should like to say to him; if he read my letter correctly he would have noted that my remarks are not *ipso facto* that that which the manufacturer gives us must be right, but that the manufacturer, having the experience of what his customers tell him, decides that they prefer and find most use for the inverted lever.

In regard to his remarks *re* the certain type of machine and its brake levers, I have had a few of these machines through my hands in the last few years, and if he will sug-

gest to the riders that an occasional drop of oil and the occasional use of a rag to clean working parts a little will remove the trouble, he will no doubt do them a service: but he does not prove that *inverted levers are wrong* by saying what he does. I can give him a much better explanation of the brakes becoming inoperative. The fault is *not* the inverted lever, but another working part, and I think I am right in saying that experiments are being made to make the brakes work better; but I repeat, we are not concerned with non-working brakes, we started on the question, "Do inverted levers cause fatigue?" Capt. Lindsay said they did: I said they did not, and gave my proofs. It is up to Capt. Lindsay to prove they *do* cause fatigue. If they do not work, then I fail to see how he gets any fatigue at all from their use, because then he cannot use them.

(REV.) R. C. MEASURES.

Sir,—The various letters *re* "Inverted Control Levers" are very interesting, but I feel sure that if the people who condemn them had in the first place made sure that the wires did not foul anything, and had afterwards periodically greased the get-at-able parts, they would not have had much trouble with them.

Personally, I much prefer the inverted type: it seems easier to manipulate, the wires do not foul, and they look much neater. The hooking effect mentioned by several is an advantage, and, last but not least, one can always grab the lever first time and be sure of it. With other types one sometimes has to feel for the lever, owing, generally, to its having twisted itself on the bar.

Granted an outside wire is more easily renewed, but if the inverted is looked after it should last the machine out.

The chief trouble seems to be chafing wires and nipples shearing their solder. Manufacturers would do well to attempt to eliminate these defects, as, although they are minor details, they often cause great inconvenience.

OOJAH.

#### IXION, WHARFEDALE, AND THE FLAT TWIN.

Sir,—I did not intend to impose upon your tolerance again with regard to the above subject, but I will assure you that this is my final expression of opinion in the matter.

My intention is not "to raise any further obstacle in the progress of the flat twin," for I am full of contrition for my past misdeeds, but I should like to offer one or two suggestions on the subject of technical criticism.

Sound technical criticism should neither evade the point at issue under cover of humour or literary effect, nor should it involve too many side issues. For instance, does my position in civil life in any way influence the qualities of the type of engine under discussion? No? Well, then, why trouble either about it or my presumable ignorance of the "sweetness of the uses of advertisement"?

When I discuss engines I hate to be switched off, by way of Grecian mythology, into mid-Victorian verse. I cannot attune myself to the new atmosphere, and am consequently left behind.

Perhaps the chief reason why the ideas of "Ixon" and myself are thus diametrically opposed is that we are both cranks and both amateurs—he an expert journalist dabbling in automobilism, and I a plain mechanic dabbling in journalism. If I could possibly imagine a personal discussion between us, I think we should each begin to consider the other quite a decent sort of chap. The world must be the poorer, however, because of the impossibility of such a

meeting, for "Ixion" is "quite an opulent person," whilst I, alas! am merely a very insignificant person—doing my insignificant bit amongst several million more.

WHARFEDALE.

#### AVERAGE SPEED.

Sir,—I was very interested in "The Critics" on average speed. Thirty miles an hour take "some" doing on a long journey. Recently I went from Newcastle to Barrow, *via* Hexham, Whitfield, Alston, Penrith, and Kendal. I passed the Central Station at 10.20 a.m., and arrived at Penrith at 12.35 p.m.; left Penrith at 12.50, and arrived at Kendal at 1.35. Leaving Kendal, by a mistake I went through Milnthorpe, reaching Barrow-in-Furness at 3.20. The distance by speedometer was 128 miles. At no part of the journey was I asleep on the road, I can assure you. On the return journey I left Barrow at 9.30 a.m., and arrived at Penrith at 12.3 p.m. At Kendal the back tyre went down, and, on dismounting I found the valve rubber had gone. I replaced this with new, bought a reserve at a

G. T. Wilkinson and his 3½ h.p. N.U.T.-J.A.P., of which he speaks in the accompanying letter.

garage, and took the road through Carlisle, arriving at that place at 12.40 and Newcastle Central Station at 2.50. The distance by speedometer was 135 miles. Although I was travelling at forty miles an hour for the greater part of the journey, the average fell considerably below thirty miles an hour.

My mount is a 3½ h.p. N.U.T.-J.A.P., 1914. Since the enclosed photograph was taken I have removed the speed gears and put in a fixed back hub, gear 4½ to 1.

The machine ran well during the whole journey, and the back tyre valve rubber going was the only trouble I had. In all the total distance was 306 miles, and I used about three and a half gallons of petrol.

As I was passing a car on Shap a sheep bolted across the road, but by slightly swerving I avoided what might have been a nasty smash. As it was, its head hit the rear of my machine.

G. WILKINSON.

Sir,—I was much interested in reading the different letters on average speeds, and I should like to add my own experience.

The trip was undertaken three weeks ago from London to Ilfracombe, *via* Dorchester and Exeter—234 miles. The machine was a 1915 3½ h.p. Rudge-Multi, having myself on the saddle and a friend on the carrier. The luggage consisted of four gallons of petrol (one tin strapped on the tank), a Rudge front wheel, front fork, shackles, and silencer.

We started at 6.20 a.m., and arrived at 4.20 p.m., stopping more than one hour on the road for breakfast, lunch, and refills. Our running average, therefore, worked out at 26 m.p.h.—not bad considering the load.

Coming back, we were on two machines, both Ridges, and from Exeter averaged 38 m.p.h. for two hours. Night then compelled us to stop.

I might add that my motor cycle has done now about 24,009 miles, and runs perhaps better than ever. I cannot be convinced that, while machines such as these are still made, the flat twin can wipe the good old single off the market. Usual disclaimer.

A. BRESLAU.

#### COURTESY ON THE ROAD

Sir,—On Sunday, August 12th, my friend had a misfortune on the road five miles from Wolverhampton. Accompanying him were his wife and child. A gentleman, I believe from Tipton, riding a B.S.A. and sidecar, who had also two lady passengers, was going in the opposite direction, shedding his own passengers, and volunteered to take my friend's wife and child back to Wolverhampton, which he did. Also a gentleman on a Harley-Davidson offered assistance. I thank both the gentlemen through the medium of your paper.

B.O. 1195.

#### POLICE INTERFERENCE.

Sir,—In view of the inconvenience and irritation suffered by some of your correspondents at the hands of irresponsible officials on the question of "pleasure" motoring, I would suggest that you should have printed for sale cards bearing the following inscription, to be displayed in a prominent position on car or motor cycle:

#### NOTICE.

The petrol used in this motor has been issued by the authority and with the approval of H.M. Board of Trade (Petrol Control Department), under licence No. — of —, after prepayment of the full Excise duty, for use at the absolute discretion of the owner.

If everyone concerned carried such a notice I think we should have little further trouble.

H. A. BROMLEY.

#### HEATED CRANK CASE.

Sir,—I read your correspondence and questions and replies. Your friends often complain of hot crank cases. I have not seen it suggested that tight main bearings or badly aligned shafts may account for this.

But in my own experience with an engine whose crank case got hot—too hot to sit on—in less than four miles, and absolutely stopped, the trouble was traced to the extra tight fit of the main ball bearings in the aluminium housings.

This engine puzzled the testers for weeks. It was tried on the road so often that the belt and saddle showed heavy signs of wear. We used to call it "Our friend the dud." When the bearing housings were freed it would run anywhere, cool as a cucumber, and stand high gear splendidly.

Now for the reason. The standard diameter of the housing was determined to suit the F. and S. ball bearings, which have a substantial outer case. But Skefko bearings which have a double swivelling case of same diameter were fitted, hence much weaker—so that a housing which was merely a force fit on F. and S. jammed the balls on Skefko.

This was the most obvious example I ever tackled, but the same treatment has cured many others. In fact, the best reply to the old wheeze "What makes an engine konk?" seems to be "Tight main bearings."

It is most difficult to detect overload of ball bearings by hand. It only shows up at high revolutions; hence a loose fit is to be preferred.

TITUS.

#### SIDECAR CONSTRUCTION.

Sir,—I should like to point out to your readers that to my mind the streamline sidecar suggested by your corre-

The Winson sporting type of sidecar referred to by G. Whiteley.

spondents is already on the market, viz., the "Sporting Winson." This model covers nearly, if not all, the points raised—streamline, sporting, well sprung, comfortable, and very roomy. The Winson tail is also equipped with a large locker, which enables one to carry a full tin of petrol, tools, etc. I have no connection with the makers, but write as a very satisfied rider for four years.

GEO. E. WHITELEY.

### ACTION AND REACTION ARE EQUAL AND OPPOSITE.

Sir,—Perhaps the following will make it clear to Mr. T. Rae that "Mohandis" was quite correct in his statement that "the road exerts an equal and opposite reaction on the tyre" (provided the wheel does not skid).

The wheel may be looked upon to consist of an infinite number of levers, each having the point of contact as the fulcrum, and coming into action in turn.

In the sketch,

AB=Radius of belt rim.

BC=Radius of driving wheel.

B=Hub.

C=Point of contact.

E=Effort of engine.

R=Resistance to motion of machine.

Now, if  $(E \times AC) = (R \times BC)$ , an equilibrium results, and the machine is at rest.

But if  $(E \times AC)$  is greater than  $(R \times BC)$ , the resistance (R) is overcome, and motion is transmitted to the machine via the hub (B). A.G.M.

Sketch illustrating A.G.M.'s remarks.

### ROADS AND ROAD TAXATION.

Sir,—I note in *The Motor Cycle* of August 2nd you devoted a short article to the question of concrete roads, and the growing necessity for long-delayed repairs to many which have badly deteriorated since the war began.

What I would like to urge is that, before any extensive repairs are commenced, involving a considerable expenditure, steps should be taken, and without delay, to render liable for road tax all motors or mechanically propelled vehicles. I believe I am correct in stating that the Motor Car Act of 19— took no cognisance of motors for commercial purposes, as they were at the time more or less in their infancy. Since then there has been an enormous increase, ranging from the ponderous char-à-banc and motor 'bus down to the tradesman's light delivery van. All these, I understand, are running untaxed both for roads and petrol—in other words, causing the bulk of the wear and tear and contributing nothing towards making it good.

The present Motor Act should be cancelled as out of date, and a new one passed, providing for the taxation of all motors using public roads. The present method of rating by engine power is open to much objection, and might with advantage be abolished in favour of making weight (car, etc.) the basis for arriving at a proper and reasonable amount of taxation. Motor cycles should be rated according to their value, with a fixed maximum, thus doing away with the manifest absurdity whereby an auto-wheel pays as much as an 8 h.p. twin machine. After the war there should be a combined effort made by all the private motoring organisations, from the R.A.C. downwards, also all road authorities, to bring about the inclusion of that class of motors at present exempt from road taxes.

In Ireland, with its scanty railway system and comparatively few trains, the motor lorry or waggon has been largely adopted between the industrial centres and outlying towns, by reason of the great saving of time and less handling of goods conveyed, the result being the main roads have suffered extensively of late years, and on some roads, owing to inferior material, any improvement effected by steam rolling is of short duration, and barely worth the expense; yet these 3 and 5 ton vehicles, unless I am utterly misinformed, pay nothing in compensation for the damage they do. Personally, I approve of and willingly pay my road tax, but it is certainly a rank injustice that the burden of taxation should not be shared by all alike.

Trusting my views may meet with the approval of your readers, and elicit their opinions and suggestions.

Belfast.

R. G. LINDSAY.

### THE POST-WAR SIDECAR.

Sir,—As a family man I have a natural interest in post-war sidecar machines, and, not being overburdened with this world's goods, wish something not too expensive or luxurious, but capable of hard and sustained service. To meet these requirements I would suggest a specification as follows:

Engine, single-cylinder 550 c.c. water-cooled, with radiator and water jacket combined as in the Green-Precision (but preferably not with both valves overhead), an outside flywheel, and gear box forming an integral part of the crank

case. The gear box should be in front, so that advantage may be taken of the longer belt-drive thus afforded, and there should also be the necessary reduction between engine and gear box to enable a large pulley to be used. The magneto, being ousted from its usual position, would be placed in rear of the cylinder, which is the better place from the point of view of protection. The engine pulley should be on the right-hand side, so that the belt is easily accessible, and the outside flywheel between the engine and sidecar, and so well protected.

The combination of water-cooling, outside flywheel, and long belt drive should make for a sturdy and smooth-pulling engine.

JOHN V. L. HALL, Lt. R.F.C.

Sir,—Surely many cases of unfair allowances of petrol, made through the existing system of distribution, whereby petrol licences are issued by one office in London, could be remedied if riders were granted their petrol cards by the same local authorities from whom they now obtain their driving licences. If this course were adopted, no doubt it would be easier for those who were entitled to a reasonable allowance for important business use to convince these people (who would already know the applicant and his affairs) in a personal interview than in many weeks of correspondence.

Your article on "Design of Four-cylinder Motor Cycle Engines" is interesting to one who has sampled every type of motor from 1½ h.p. Minerva upwards, and I for one am firmly convinced that there is a future for someone who can place a four-cylinder combination on the market to the following specification for about £65: Engine, 10 h.p. *monobloc*, two speeds, shaft drive, Scott radiator; the whole built in one unit, i.e., sidecar, chassis, and cycle; the power unit and gears fashioned after the Ford car principle; the chassis on car lines, and without any forks and stays to surround the wheels. We could then have real detachable wheels, and a serviceable all-weather combination which could be cleaned with a hose if necessary.

Our makers must break away from the conventional design before finality in design can be reached, and build us a complete machine instead of assembling an accumulation of other people's specialities. We must not lag behind our American competitors, as we shall want a real motor cycle for the million (not the millionaire) as soon as hostilities cease.

Cottingham.

FORSYL.

### WHO SHOULD HOLD DRIVING LICENCES?

Sir,—I have been greatly interested in the correspondence in *The Motor Cycle* re granting licences to persons who have partially lost certain of their faculties, especially those who are minus the vision of one eye.

With regard to my own case, I may say that, owing to an accident during childhood, I was deprived of the sight of the left eye. Of those early years I can give very little information as regards my sight, but during the last seven years before joining the Army, I had been an enthusiastic motor cyclist, and had ridden machines bearing the names of most of the well-known makers, and during that time had only had one accident, and that through no fault of my eyes, but through another person's carelessness and neglect of the rules of the road.

My right eye is slightly myopic, but that is corrected with glasses.

I believe I am right in saying, and I have the information from a qualified optician, that when the sight is lost from one eye, the other, in most cases, if in a healthy condition, will automatically adjust itself in time, and that the person afflicted will be almost as good a judge of distance from one point to another as those more fortunate individuals who possess sight in both eyes and can obtain a true stereoscopic effect, and certain of whom wish to deprive such people as myself of one of the greatest pleasures in life.

During my riding experience I have had some very narrow escapes, and saved myself solely by estimating distance, which must have been somewhere near correct, otherwise I should not be alive to-day.

I certainly hope therefore that the authorities will not deprive people similarly afflicted as myself of the privilege and pleasures of motoring when things settle once more to their normal conditions, provided they can prove their driving capabilities. I hope this letter will reach you ere this discussion is entirely forgotten.

Salonica. (PTE.) EDGAR G. WATKINS, R.A.M.C.

# THE Critic

## Fireside Chats on Motor Cycle Problems

### POWER versus WEIGHT.

"I AM looking forward to seeing what sort of an impression the big American twins make among our D.R.'s in France," the Manufacturer said, thoughtfully. "It will be particularly interesting to note how they compare with the popular British type during the winter months, and it is really a mighty important matter. The war is the competition world of to-day, and if before very long everyone is talking about the suitability of the big American machines out there, it will have a great effect on our Overseas market."

"The machine that will do well in France will doubtless do well in the Colonies," agreed the Journalist, "but I do not think that it follows that the best machine for France is also the best machine for the Colonies."

The D.R. also held this view. He said that in his opinion the  $3\frac{1}{2}$  h.p. single is the best machine for France, but he would prefer the big twin for the Colonies; while the Novice pointed out that from his point of view the most important point on which the big twin scored for Colonial use was in its universal adaptability. "A standard type of sidecar can be hitched to it at a moment's notice, thus widening its sphere of usefulness," he pointed out, "but this does not apply to Army work."

"It certainly would not apply to war work," announced the D.R. "Despatch riders don't want sidecars, and machine gun men and the commissariat departments don't want solo mounts. There is no object in hauling a needlessly heavy and hungry mount over thousands of miles solo because someone may some day wish to attach a sidecar to it. Mind you, I do not wish to depreciate the big American machine, which is a type of mount I favour."

"Well, I do not," stated the Manufacturer. "It is all right when one is in the saddle, but there are times when one has to handle the machine out of the saddle. It is then an unwieldy burden."

"That has never bothered me," said the D.R. "If you old fogeys will push your machines about instead of straddling them, you can't blame the machines because you don't like it. I know that the opinion of the average British rider is that the big American is difficult to handle, but if this were so, how would it be possible for the Americans themselves to accomplish such marvellous overland records? Look at Bedell's record from Los Angeles to New York—3,276 miles in 7 days 16 hours, partly over appalling country! Unless the American machines were cut out for such work, how could it be possible?"

"For such records I agree that you must have high power," replied the Journalist. "It would be impossible to maintain a high average over rough country without it; impossible, too, if the engine were overworked throughout the journey. But this in no way satisfies anyone that the type of machine is suited to the requirements of the everyday rider amidst such conditions."

"But it proves this," quickly retorted the D.R.—"that the machine was not exhausting to ride. You know as well as I do that a record of this sort is a record of human endurance as much as anything, which shows conclusively that the handling of big solo mounts is chiefly a matter of knack."

#### The Elderly Rider.

"There appears to be some sense in that," the Journalist admitted; "but, look here, I have ridden these big machines abroad and in the most strenuous competitions at home. I have ridden them through swamps and along the beds of rivers, and I can assure you that under such conditions I have felt a very real desire for something light and low geared."

"And so have I," agreed the Manufacturer. "One must bear in mind that not all motor cyclists are of the despatch rider order—young, perfectly fit, practically living on their machines. That type of man naturally loves a big twin, but the opinions of despatch riders must not entirely rule the roast."

"But his opinion will carry big weight in the Colonies," pointed out the D.R., "because there a machine is regarded solely as a business proposition. There is little pleasure riding done, and the only choice in the matter is between the big twin and the light four-wheeler. The elderly rider chooses the car every time, and so need not be considered."

#### What about Wheel Slip?

"Suppose we discuss the actual machines?" suggested the Journalist. "There is no doubt that the big engine scores tremendously when it comes to cases of plugging through deep sand on an up grade or through heavy mud. It can do this at quite a normal load, whereas the  $3\frac{1}{2}$  h.p. is very fully loaded under such conditions, and therefore more likely to give trouble. That is where the big engine scores, but no one loves it for its weight. You get one of these big Americans properly bogged amidst really Colonial conditions, the engine firmly jammed against the ground, and you jolly soon revise your ideas as to the suitability of heavyweights for such work."

"Hear, hear!" muttered the Manufacturer. "I have never quite seen the object of these huge engines for regions where the speed at which one travels is entirely governed by the condition of the roads. On our roads there is some fun to be had with a powerful twin, but in countries where the roads are of the pioneer order it seems to me that one is burdening oneself with an unnecessary weight of machinery to drag through the swamps. With a British  $3\frac{1}{2}$  h.p. machine you have power enough to propel the wheel anywhere that wheel grip is possible. When the wheel begins to spin it doesn't matter a straw whether you have  $3\frac{1}{2}$  b.p. or 9 h.p.—in fact the light machine stands the better chance of extracting itself."

"Not if it be provided with 26in. wheels and the twin with 28in.," argued the D.R. "Now just listen to this. I once took part in a moorland trial—river beds, peat swamps, etc. I tried to get round in advance on a lightweight machine, but though I had power in hand I was bogged at every swamp, and it took me three and a half hours to do twenty-eight miles. The little machine simply had not the weight and mud-plugging capabilities to carry it through. On the day of the trial I rode a heavy  $3\frac{1}{2}$  h.p. chain-driven single, and got cleanly through all the swamps—simply ploughed straight across them by sheer momentum. This shows that weight is at any rate of some advantage when the conditions are really bad."

"Now—wait a minute, I've not done yet. I'll tell you another point on which the big low compression slow-running American engine scores. You can throttle it down till it just ticks over, delivering an even driving motion to the rear wheel, almost irresistibly. It will keep on ticking over like that as long as you like, and you can walk alongside, allowing the rear wheel to spin in the mud if it wants to."

"That is purely a matter of flywheel weight and a pilot jet," pointed out the Journalist. "And you can do exactly the same thing with a British single. Personally, I have found that a good British single with its hand-controlled clutch is infinitely preferable to the big American twin when it comes to wallowing alongside with the engine just ticking over."

"Of course, you can," supplemented the Manufacturer. "All you want for that kind of work is a heavy flywheel, a decent carburetter, and a handle-bar clutch."

"Do you not think," modestly interposed the Novice, "that it is not so

### The Critics.—

much the big engines of American machines which specially appeal to Overseas riders, but the other points of design—sufficient ground clearance, large wheels and tyres, positive drive, loop frame, and a machine which is not abnormally heavy for its power? Then, again, the matter of price is the most important factor of all. My opinion is that if one could buy a popular Yank with, say, a Triumph or Sunbeam engine stuck in the frame, it would sell better Overseas than the present Yank with a Yankee twin engine. Find me a pipe cleaner."

But the D.R. still shook his head. "The Americans do not stick on an

extra cylinder just for the fun of the thing," he said. "It is difficult to describe how truly abominable the roads really are in some unsettled portions of the world. One must have a slow-running engine with a big reserve of power—an engine which will stick it for hours. I have ridden a  $3\frac{1}{2}$  h.p. single—one of the best—in Canada, and I tell you that I have met conditions so vile that it was necessary to get off and let the engine cool every other mile. That was a modern three-speed machine, and on a big two-speed American I have made the same journey without trouble."

"What about France?" queried the Journalist. "What would you have said had they rigged you out with big twins?"

The D.R. thought a moment. "We could have done with the extra cylinder so far as more power and improved torque were concerned," he finally acknowledged, "but we did not want the extra weight."

"Did you think the extra power and improved torque would have been worth the extra weight?" demanded the Manufacturer.

Again the D.R. pondered, but this time the question went unanswered, for at that moment a happy diversion was caused by the Novice, who, having failed to induce the cushion to yield a feather, was attempting to stuff the end of the ornamental blind cord down the stem of his pipe.

### THE COUNTRY DOCTOR.

It is hardly probable that doctors will suffer by a curtailment of their petrol supplies, but should an unlikely thing happen, many who now run cars will turn to the sidecar, just as the country practitioner in the photograph has done. Besides consuming less petrol there is the greater likelihood of repairs being more easily performed at home than would be the case with a car—an advantage in these days of labour shortage. Incidentally, the fourteenth century court house depicted has great historical interest. It is situated at Long Crendon, near Thame, Bucks. Here Walter Beauchamp, the Great Steward of Queen Catherine, Consort of Henry V., held courts from the first to the eighteenth year of the reign of Henry VI.

## How Manufacturers are Imposed Upon.

ON a recent occasion Mr. W. H. Wells (The Hendee Manufacturing Co., Ltd.) showed us a glaring instance illustrating the manner in which unscrupulous people often impose upon manufacturers by attempting to get defective goods replaced free of charge. In this case the culprit reported to the company an accident which happened to his machine, a 1915 5 h.p. Indian, fitted with a light sidecar and ridden by his son. While travelling at a slow speed the front down tube and lower horizontal tube broke, with the result that the machine was overturned. In a letter to the firm he expressed his surprise at the accident having happened, especially as the machine had had very little use, and had never been subjected to anything that would cause extra strain. In consequence of this letter the company suggested that the machine should be stripped and the frame sent to them for inspection.

On its arrival we were invited to go and see it, and found that the breakages

were as stated in the customer's letter, but, far from the machine having had very little use, it had been subjected to all sorts of unfair strains. It had evidently been broken before at the places mentioned, and had been brazed, while there were traces of the points fractured having been exposed to enormous heat. Moreover, the previous repair marks were clearly shown, indicating where the frame had been touched up with red paint, which showed clearly, distinctive from the standard enamelled colour.

#### Asking too Much.

The owner had no evidence of the amount of use to which the machine had been subjected, as he did not even know from what agent it was bought, nor the date. He merely had watched the way in which it was treated during the time that it was in the possession of a friend of his, and previous to that date, of course, he knew nothing about it. In one of his last letters he states that he

was surprised that a company with such a name should be unable to replace the frame, the tubes of which, in his opinion, were remarkably thin. Having personally inspected the breakage ourselves, we would say that the tubes are, on the contrary, of ample thickness and stability. To expect makers' guarantees to hold good indefinitely is asking too much.

### IMPORTANT NOTICE.

#### GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD.

# QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of the envelope, and should be kept distinct from questions bearing on technical subjects.

## Oil-proof Plug Wanted.

I am constantly troubled with the sparking plug of my two-stroke oiling up. I use a two-point plug with heavy electrodes. —J.H.

Bend one of the points away from the centre electrode, so that it sparks across one gap only. Try using less oil. The best type of plug would be one having fine platinum wire points.

## For Sidecar Use.

I have bought a 6 h.p. twin Rex with automatic inlet valves. Would you kindly let me know if it is powerful enough to take a sidecar with a N.S.U. gear fitted to it? It has a Roc handle starter also. The engine is in very good order, and a Binks 1917 carburetter is fitted.—F.C.

If the engine is in really good condition the machine should easily take a sidecar in normally level country, but with an old engine everything, of course, depends upon the care, or otherwise, with which it has been used. The only way to form an opinion as to whether or not the machine will take a sidecar is by trial on the road.

## Four-stroking.

Can you give me any information as to how to eradicate the four-stroking of a 2½ h.p. two-speed, two-stroke, fixed gear motor cycle fitted with an Amac carburetter, bought new in 1916? The four-stroking occurs at speeds of 20 m.p.h. and under. The jet used is No. 26, as put in by the makers. Even with the air full open it is no better than in any other position. The crank case is air-tight, and so are all the joints. The plug, jet, and carburetter are clean. The four-stroking occurs on the level, and disappears on slight grades. Over 20 m.p.h. the machine two-strokes with regularity on the level as well as up hills. I have tried a larger and a smaller jet, but with worse results, if anything. The machine has only done about five hundred miles up to the present. Any help to cure this trouble will be very gratefully accepted.—H.W.B.

The trouble of which you complain is very hard to cure. It may often be improved by fitting a smaller jet and hot air intake. The fact that the engine will take in air all the time seems to indicate that the mixture is too rich. Over-oiling also will cause four-stroking. The trouble will probably diminish after the machine has been running a little longer.

## Use of Foot Brake.

Does it harm a motor cycle in any way to put on the foot brake slightly when rounding a corner, instead of raising the exhaust valve, as my 2½ h.p. motor cycle does not gather speed again quickly after lifting the exhaust?—F.V.C.B.

The correct way is to throttle down when using the foot brake, not to use the latter against the power of the engine. This would cause excessive wear of the brake block or lining; otherwise no harm would be done. Do not control by means of the exhaust lifter, but by manipulation of the throttle.

## Fitting Disc Wheels.

(1.) I have a 1914 T.T. Scott machine, and propose fitting disc wheels to it. Will this affect the steering at all? (2.) Can you suggest any suitable type of vaporiser for this machine? I have a Binks carburetter. (3.) Do you consider that a 250 miles run (from London to South Wales) would be too far to go in one day?—J.D.

(1.) The fitting of disc wheels to your machine will not affect the steering, except perhaps in a very strong cross wind. (2.) No special vaporiser would be necessary if you fit a thoroughly efficient hot air intake. This can be done by carrying a brass or copper pipe through the silencer and continuing it upwards to the carburetter. (3.) 250 miles in a day is a long run, but if you start early in the morning it can be done without hardship.

Mr. J. Muscat, proprietor of the *Malta Herald*, about to start on a shooting expedition. He says that motor cycling is on the increase in the isle of Malta—or "Flor del Monda" (the flower of the world), as the natives call our Mediterranean Possession.

## Petrol Consumption.

I am a constant reader of your paper, and continually come across letters therein telling of extraordinary miles per gallon on various makes of machines. I own a 1916 Royal Enfield combination, 6 h.p. twin, and am doing 125 miles to a tank of petrol, i.e., two gallons less one pint. I wish to ask if you will kindly inform me whether this is fair. If not, how can I improve on it?—C.L.D.

If you are getting approximately 60 m.p.g. with the outfit fully loaded you have nothing to complain about, and we doubt whether you will be able to improve very much upon this. It is possible for a good tuner to obtain higher results, but it is more a matter of individual judgment and a combination of small points that it is due to hard and fast rules.

## Misfiring.

I have a 2½ h.p. 1911 Douglas, fitted with automatic inlet valves. My trouble is misfiring in the rear cylinder, and I am unable to climb the slightest gradient on top gear, and am also suffering from excessive fuel consumption. I have changed over the inlet valves, and also the plugs, and fitted new piston rings, but still the trouble is confined to the rear cylinder. I am running on naphtha, and have a hot air pipe from the cylinder to the carburetter, and also a gauze in the intake. I used to get good results until lately. I should be glad if you would help me to locate the trouble.—W.B.T.

We should recommend you to check the tappet clearances and lift thoroughly in the case of all four valves, and, if you find these clearances are correct, fit a stronger exhaust valve spring. It seems to us most likely that the tappet of the exhaust valve in the rear cylinder is in need of adjustment. You might also look to the carbon brush of the cylinder which is misfiring, and try the spark at this cylinder by running the engine on the other cylinder with the back plug resting on some metal portion of the frame. If the spark is intermittent, you will know the ignition is to blame. Make sure the back valve is not periodically gummed up with oil by over-lubrication. A certain amount of trouble must be expected when running this type of engine on heavy fuel, the automatic inlet valves permitting certain fluctuation in the charge.

### A Matter of Choice.

**?** (1.) What is the speed capability of the 4 h.p. Douglas when tuned up and riding solo? (2.) Would the 2½ h.p. Douglas be suitable for a journey, say, from London to Newcastle? (3.) Which of the above two is the better solo mount?—K.P.

(1.) Speed capabilities are dependent upon engine tune. If adjusted for racing, it is possible to get a maximum speed of somewhere between sixty and seventy miles an hour on the track with a 4 h.p. engine, and very nearly the same speed on the road. (2.) Quite suitable. (3.) This is purely a matter of taste. The 4 h.p. is, of course, faster and more powerful, and probably preferable for very long journeys.

### Improving Consumption of Old Machine.

**?** Will you let me know if it would be of any advantage to me if I fitted an up-to-date carburettor on a 1912 Triumph? The machine runs very well, but is not very economical. It is a 3½ h.p. fixed engine.—J.W.S.

As you would experience considerable difficulty in obtaining an up-to-date carburettor, and the improvement you would make on the original 1912 model would be very small, we should not recommend you to make any alteration. You can tune up the engine and carburettor to be quite equal in economy by experimenting with the size of the jet and choke tube. Also make sure the slides are not excessively worn. If worn, it would be better to renew them.

### Almost a Mystery.

**?** My mount—a 4 h.p. twin Precision engine, side-by-side valves, Bosch magneto—is an exceedingly fast machine, and ran well till recently, when without any alteration to anything it suddenly struck work, and has never run since except on the front cylinder, which fires strongly. I have taken down the engine, cleaned the carburettor and magneto, but no improvement. Compression on both cylinders is good, rings not sticking, valves opening correctly at the right time and not sticking, valve lifter free when running, carburettor (B. and B.) clean, no air leaks, jet correct size. Gas is reaching the back cylinder, but exhausted into the silencer unexploded. Silencer pipe removed altogether and the engine has been tested at all throttle and spark positions. Sparking plugs in order—six makes tried. Magneto and valves are both timed correctly and working properly; carbon brushes not sticking and clean; points the correct break; high-tension wire not shorting.—A.D.

It is very difficult to suggest a possible cause of the trouble, as you seem to have checked everything. We suppose you have made sure that a spark is actually occurring at the plug points of the back cylinder? If not, you had better do so; you may have a broken high-tension wire. Examine the valves and valve guides for leakage, and look out for cracks in any part of the engine. Make sure there is no impediment in the induction pipe,

and also that the carburettor slides have not moved their position. Examine magneto thoroughly, looking out for loose, cracked, or broken parts—especially carbon brushes. Make sure that tappets are correctly adjusted.

### Worn Pulley.

**?** I have a Zenith gradua gear. The belt begins to tighten when down as far as it will go (very tight), but when on high gear the belt is very slack. What is the cause of this?

The probable cause of the tight belt on low gear and slack belt on high gear is that the machine has been ridden mostly on high gear, which has worn the pulley flanges, so that the belt tends to drop deeper into the groove on high gear. Thus it is robbed of its full range of action.

### Tyre Trouble.

**?** (1.) Would a Grado heating jacket fitted to Senspray carburettor be sufficient for running on substitute or paraffin (after starting on petrol)? The machine is a 1912 3½ h.p. B.S.A. (2.) I recently fitted a new 26in. x 2½in. extra heavy Dunlop outer cover and a new (same size) Michelin butt-ended inner tube. The inner tube on several occasions has burst. The same thing happened to the last inner tube. The spokes do not appear to project too far. Can you suggest a reason? The inner tube seems to be too long. Would it get pinched if it overlapped anywhere? The tyre is on the rear wheel.—C.B.M.

(1.) The Grado vaporiser should be quite suitable for this purpose. A hot-air intake in addition would assist. (2.) Yes, if the inner tube is not a good fit in the cover, it is naturally liable to get pinched. Try an inner tube of the same make as the cover, and see that the butt end is properly fitted together, with plenty of French chalk.

### Hot Crank Case.

**?** I have an Ivy four-stroke motor cycle fitted with a J.A.P. engine, and frequently at the end of quite a short run I find the crank case exceedingly hot—too hot to hold one's hand against. My dealer tells me that this may very likely be caused by the impure quality of the petrol now supplied, and I was wondering if this might be the case. If so, is it doing any harm to the engine to go on running while the crank case is in this state, and can anything be done to stop it?—G.R.R.

The heating of the crank case is probably owing to leakage past the piston rings. If the engine pulls well and does not consume an exorbitant quantity of oil there is no need to trouble about it, though the defect will probably cause a rapid accumulation of carbon inside the piston. New piston rings would no doubt remedy it. It may also be due to conductivity, in which case the fitting of an asbestos washer between the cylinder and the crank case will tend towards eliminating it. We do not think that present-day petrol would have this effect, though an engine runs at a higher temperature on substitutes than on petrol.

### READERS' REPLIES.

#### Remagnetising Magnets.

There seems to be a certain amount of risk in carrying out your instructions for remagnetising magnets, as given in your Queries and Replies columns in the issue of August 2nd. We would warn your correspondent not to carry out the operation for the following reasons. Three turns of No. 20 (copper) wire wound round each pole would equal, say, two yards, the resistance of which is approximately .0472 ohm, which at 116 volts would give a current of about 2,450 amps. As the fusing capacity of this wire is 70 amps., the chances of applying the current for half an hour are nil. From the above figures it will be seen that about 2,000 yards of No. 20 wire will be required to give 2.6 amps. (at 116 volts), which is the safe current capacity; or, say, 1,000 yards would be safe for half an hour without overheating seriously. The best way would be to wind as much wire on the magnets as possible, and then "flash" the circuit, which method is beyond the scope of a novice—in fact, it is inadvisable for a novice to attempt to remagnetise magnets. Care should be taken to place a piece of iron across the poles when the armature is not in place.—SPARKS AND FLASHES.

#### Timing a Small Twin.

In reply to your reader re timing a twin Moto-Rêve: (a) Set the valve cam wheel main axle and intermediate wheel to their markings, and the valve will be right. (b) The ignition for this must be fixed, the screw in the ring on contact breaker side to be in the centre of the part cut away. Turn the engine over till exhaust has closed and on till piston is at the top of cylinder. Put fibre block on contact breaker to front cam roller, and connect up the pinion wheels to magneto to the others already fixed. The bottom collector of magneto goes to the back cylinder, and the top to the front. If your reader is residing in London, I should be pleased to show him the position of the pinion wheels. I wonder if your reader could tell me where I could obtain piston rings and an ebonite collector.—J. FRETHEY.

### RECOMMENDED ROUTES.

#### DERBY TO CHADDESLEY CORBETT.—B.B.

Derby, Burton-on-Trent, Lichfield, then through Pelsall, Bloxwich, Wolverhampton, Kingswinford, Stourbridge, Hagley, Chaddesley Corbett.

#### LONDON TO ILFRACOMBE.—J.E.

Brentford, Hounslow, Staines, Bagshot, Camberley, Blackwater, Hartley Row, Basingstoke, Whitechurch, Andover, Amesbury, Hindon, Wincanton, Langport, Taunton, Milverton, Bampton, South Molton, Ilfracombe. The distance is approximately 214 miles.

#### CHAPEL-EN-LE-FRITH TO LONDON.—J.C.

Chapel-en-le-Frith, Baslow, Chesterfield, Mansfield, Newark, Grantham, Stamford, Wansford, Stilton, Biggleswade, Baldock, Stevenage, Hatfield, Barnet, Finchley, Golder's Green, Hampstead. The distance is approximately 175 miles.

## MOTOR CYCLES FOR SALE.

## Bat.

BAT Motor Cycle, C.A.V. mag., perfect condition; £8.—24, Tulse Hill, Brixton. [6912]

BAT-J.A.P. Twin, 5-h.p., mag., and sidecar; bargain, £20.—Bridges, 10, St. Ilyds Crescent, Swansea. [6881]

1914 Bat-Jap 6-h.p. Combination, 3-speed, Lucas lamps, speedometer, horn, and wind screen, a very fine and well cared for combination; 40 gns.—96, Ashbourne Rd., Mitcham. [6833]

BAT-J.A.P. 1914 8-h.p. Twin Combination, chain drive, countershaft gear, spring frame, Dunlop tyres, luxurious Bramble sidecar, apron, lamps, best order; £50.—Barratt, Garage, Worcester St., Wolverhampton. [X3855]

8-h.p. Bat-Jap, late 1913, 2 speeds and free engine, with coachbuilt underslung sidecar, fitted with wind screen, Smith speedometer, good tyres, and spares; £38/10, or offer.—Gauden, 63, Mitcham Rd., Tooting, S.W.17. [6884]

## Bradbury.

BRADBURY, 1913, 3½-h.p., 2 speeds, and new coach build; £29/10.—Motor Exchange, Horton St., Halifax. [6717]

1911 Bradbury, 4-h.p., single speed, T.T. bars; £20.—Elce and Co., 15-16, Bishopsgate Av., Camomile St., E.C. [X492]

BRADBURY and Sidecar, 2-speed gear, new tyres, good condition; owner going away; £35, bargain.—F.G., 36, Clarendon Sq., Pentonville, N. [6729]

BRADBURY, 4-h.p., 1913, F.E., clutch, Bosch, B.B., Drmid forks, Dunlop belt, in perfect running order; owner bought higher power; £20.—2, Buckthorpe St., Bolton. [X3999]

## Brown.

BROWN, 3½-h.p.; £12/10.—W. and H. Motor Co., Ltd., 287, Deansgate, Manchester. [6506]

## B.S.A.

B.S.A., 4½-h.p., 1915 combination, in 1916 condition, as new; £60.

B.S.A., 4½-h.p., brand new, actually in stock; £64.—Percy and Co., 319, 321, 335, and 337, Euston Rd., London. [6935]

COLMORE Depots 261, Deansgate, Manchester, for immediate delivery of B.S.A. [X798]

B.S.A. New 1917 Model K's in stock; £64.—Colmore Depot, B.S.A. Agents, 211, Deansgate, Manchester. [6886]

1916 B.S.A. Model H, with accessories, in very good condition; £45 cash.—Walbro Cycle Co., Saffron Walden. [6675]

B.S.A., 1915, and coach sidecar, complete, with lamps, horn, numbers, tools, in fine order; £58.—Batches, Clarence St., Kingstow. [6807]

B.S.A., late 1913, 2 speeds, free, clutch, kick start, chain drive, good order; £28; after 7 p.m.—Hammant, 63, Carlton Vale, Kilburn, N.W.6. [6672]

1917 B.S.A. Model K, with 1916/16 Montgomery sidecar, lamps, horn, and accessories, used 2 months only; £65.—Walbro Cycle Co., Saffron Walden. [6674]

1913 B.S.A. 2-speed, kick starter, with cone sidecar, lamps, horn, speedometer, perfect running order, in condition; 40 gns.; any trial.—Box 14,311, c/o The Motor Cycle. [6922]

B.S.A. 1916 1914 engine Combination, all chain, 4½-h.p., in faultless condition, best B.S.A. sidecar, Lucas accessories; £58.—Burrell, 60, Lea Hall Rd., Leyton, N.E. [6781]

B.S.A. 1915 Combination, 3-speed countershaft, all chain drive, splendid condition; 55 gns.; accept stroke part payment.—Haslam, Wheatsheaf, Newcourt St., Swindon. [6734]

B.S.A. 1916 4½-h.p. Combination, chain drive, B.S.A. sidecar, Watford speedometer, Smith's horn, P. and H. lamps, perfect condition; £65.—Fisher, Brewery House, Newcastle, Staffs. [X4091]

1916 B.S.A., chain-belt, 3-speed countershaft gear, 4½-h.p., suitable for sidecar work; price only 46 gns.; undoubtedly the cheapest B.S.A. in England today.—Julians, 84 Broad St., Reading. [Biggest light car and motor cycle dealer in the South. Phone: 1024.] [6916]

## Calthorpe.

COLMORE Depots, Birmingham, Manchester, and Liverpool, for Calthorpe motor cycles. [X799]

CALTHORPE 2-stroke, 2½-h.p., almost brand new; £23.—44, Finsbury Pavement, E.C.2. [6901]

CALTHORPE, 2-stroke, 1915, 2-speed, good condition; 19 gns.—Ealdwin, Lynton, Western Rd., onford. [X4118]

CALTHORPE-J.A.P., 2½-h.p., September, 1915, 2-speed; £25.—Peters, 18, Lofthair Rd., Harringay, London, N. [6839]

CALTHORPE-J.A.P., 1916, 4-h.p. twin combination, 3 electric lamps, very smart outfit; £63; after 5 p.m.—58, Woodfield Rd., Ealing, W.5. [6847]

CALTHORPE, 1917, J.A.P., latest model, brand new, Enfield 2-speed, in stock; 38 gns.—Wilkins, Simpson, and Co., 11, Hammersmith Rd., London. [6464]

WANTED.—Any number of FIRST-CLASS OUTFITS. Price no object. Cash immediately on acceptance; no sale or return business.

## NEW MACHINES ACTUALLY ON SHOW.

ENFIELD 1917 6-h.p. Outfit .....	£115 0
ENFIELD, 1917, 2½ h.p., 2-sp., 2-stroke	£44 0
ROVER, 1917, 3½ h.p., 3-sp. countershaft	
Combination, with Sidecar .....	£99 4/6
JAMES, 1917, 3½ h.p., twin, 3-speed .....	£69 10
JAMES, 1917, 4½ h.p., No. 6, 3-sp. Comb.	£87 2
ARIEL, 1917, 3½ h.p., 3-speed Combination	£93 10
LEVIS, 1917, 2½ h.p., 2-speed, Model E. ....	£47 10

with Sidecar .....	£50 0
ALLDAYS ALLON. All models from ...	£37 10
ROYAL RUBY. All models from .....	£32 10
MATCHLESS War Model, 7 h.p., 3-speed,	
spare wheel .....	£120 0
HARLEY-DAVIDSON, 1917, electric model,	
with H.D. "B" Sidecar, lamps ..	£140 0

## SECOND-HANDS.

ENFIELD, very late 1916, 6 h.p., Combination,	
dyna. lighting, condition very fine	£110 0
ENFIELD, 1916, 6 h.p. Combination, lamps,	
hood, Cowey speedometer .....	£84 0
ENFIELD, 1917, 3 h.p. twin, semi-T.T.,	
2-sp. model, with sporting Canoelet S.C.	£69 10
ENFIELD, early 1916, 6 h.p. Combination,	
and accessories .....	£80 0
ENFIELD, genuine 1917, 6 h.p. Combination,	
speedometer, lamp, and horn,	
scarcely used .....	£105 0
ENFIELD, 1914, 6 h.p. Combination, 3	
lamps, horn, engine just been over-	
hauled .....	£68 10
RADCO, 2½ h.p., 1912-14, great bargain	£12 10
MATCHLESS, 8B, 7-h.p. Combination,	
Lucas accessories .....	£89 10
INDIAN, 1915-16, 7-9 h.p., clutch model,	
1-T. bars, disc wheels, with lamps and	
horn, ridden approximately 1,000 miles	£55 0
TRIUMPH, 1911, 3½ h.p. model, fixed gear,	
semi-T.T. bars, and accessories .....	£20 0
TRIUMPH, 1913, 3½ h.p., 3-sp., semi-T.T.	
bars, a nice little solo mount .....	£35 0
TRIUMPH, 1914, 4 h.p., 3-speed, Starkey-	
Archer gear, Millford Sidecar .....	£48 10
ALLON, 1916 model, 2½ h.p., 2-sp., hand	
clutch, just overhauled by makers ..	£25 10
ALLON, 1917 model, 2½ h.p., 2-sp., hand	
clutch, full kit tools, and Stewart	
warning horn, ridden 200 miles only	£43 0
NEW HUDSON, 1913, 3½ h.p., 3-sp. Comb.,	
with lamp, horn, etc. ....	£39 10 or near offer.
A.J.S., 1915, 4 h.p., 3-sp. Combination, all	
accessories, in excellent order .....	£20 0
O.K. JUNIOR, 1914, 2-stroke .....	£20 0
JAMES, 1913, 3½ h.p., clutch model, with	
accessories .....	£25 0
DOUGLAS, 1914, 2-sp., kick-starter model,	
in fine condition, but needing slight	
repair .....	What offers?
LEVIS 1915 Popular Model .....	£10 0
ENFIELD Family Sidecar .....	£10 0
WATSONIAN Lightweight Sidecar .....	£10 0

WANTED.—SALESMAN and JUNIOR SALESMAN. Progressive position to right man. Easy berth, with plenty of scope. Wages immaterial.

WANTED.—FORD VAN, not earlier than 1915, also B.S.A. or Standard Auto-Wheel.

WANTED QUICKLY.—HARLEY-DAVIDSON, Combination or Solo, 1915-16, either model. Also B.S.A., Solo or Combination.

Owing to the printer's error in the issue of the 16th inst., an A.J.S. at £75 should have been £84; a Harley-Davidson at £75 should have been £75; a Matchless at £25 should have been £95.

RUDGE, I.O.M., special fast machine, as new; £50.

RUDGE Multi, 1914, speedometer, perfect order; £30.—Percy and Co., 319, 321, 335, and 337, Euston Rd., London. [6937]

RUDGE Multi 3½ h.p. 1913 Combination; £43.—W. and H. Motor Co., Ltd., 287, Deansgate, Manchester. [6504]

LATE 1914 5-6 h.p. Rudge Multi, complete, excellent condition; £36; or near offer.—38, West St., Reigate, Surrey. [6831]

1914 T.T. Rudge, N.S.U. gear, electric lamps, horn, appearance as new; cheap; what offers?—Write, Mayes, 198, Ancona Rd., Plumstead. [X4052]

RUDGE, Grado Multi gear, late 1912, 3½ h.p., fully equipped, fine running order; £25.—Wellbroy Garage, Woodford Rd., Forest Gate. [6904]

RUDGE Multi, 1913, 3½ h.p., speedometer, fully equipped, good condition, reliable; £28.—Wellbroy Garage, Woodford Rd., Forest Gate. [6903]

RUDGE Multi, 1915, 3½ h.p., speedometer, fully equipped, very fast and fine condition; £43.—Wellbroy Garage, Woodford Rd., Forest Gate. [6902]

RUDGE Multi Combination, hand clutch, kick start, all accessories, perfect condition; any trial; £38; or exchange good lightweight.—C.S., 497, Old Ford Rd., Bow. [6701]

RUDGE Multi, 3½ h.p., special Millford coach sidecar, hood, screen, 3 lamps, spares, tyres, nearly new, thoroughly overhauled and cleaned, condition excellent; really cheap, 44 gns.—Chantry Motor Works, Hatch End, Middlesex. [X4029]

RUDGE Multi, 1913, fitted for substitute, excellent condition, £33/5; Isle of Man engine model, fitted with large head lamp, and Klaxon mechanical horn, 1914 model, £30/10; Multi, in excellent condition, 1914, practically new tyres, T.T. bars, £31; extended payments or exchange.—Service Co., 292, High Holborn, London. [X4138]

## Scott.

COLMORE Depots, Birmingham, and Manchester, for Scott motor cycles. [0806]

SCOTT, 2-stroke, 2-speed, kick starter, wants putting together; bargain, £16.—Reilly, 215, Overgate, Dundee. [6652]

SCOTT, late 1914, Binks 3-jet, lamps, etc., and spares, handsome machine; £40.—French, Station Rd., Hykeham. [6685]

SCOTT, 1914, and sidecar, 2-speed, kick starter, 2-cyl. 2-stroke, Binks carburettor, Stewart speedometer, Palmer cord tyres; £65; extended payments or exchange.—Service Co., 292, High Holborn, London. [X4148]

## MOTOR CYCLES FOR SALE.

## Service.

**SERVICE**, 2½ h.p., 2-stroke Peco engine, chain and belt drive, 1915, a very reliable proposition, 2-speed, Harcourt extra cooling fins; £35; extended payments or exchange.—Service Co., 292, High Holborn, London. [X4141]

## Shaw.

**3 1/2 h.p.** Shaw, Saxon forks, Amac, Helleisen's ignition, 32 running order; bargain, £5/15.—Box L4308, c/o The Motor Cycle. [6921]

## Singer.

**3 1/2 h.p.** Singer, 3-speed, clutch, kick starter, perfect; £2 £32.—95, Shaftesbury Rd., Hammersmith, W. [6708]

**SINGER**, 4½ h.p., 2-speed, free engine, fitted with sidcar complete, good running condition; £38.—Taylor, Westbank, Hanow, Essex. [6838]

**4 1/2 h.p.** Singer, 2-speed, clutch, Bosch, new tyres and £2 belt, coachbuilt sidcar, guaranteed in sound condition; £30.—4, Doolittle, Hemel Hempstead, Herts. [6655]

**SINGER**, 4½ h.p., 1915, Canoelet sidcar, gear box, clutch, kick starter, wind screen, spare valves, etc., faultless; £37/10.—25, Warham St., Kennington Park. [6779]

## Sparkbrook.

**1915 Sparkbrook**, 2-speed, 2½ h.p., Lucas horn and lamps, perfect running order; £25.—Rev. Lion, Albert Rd., Alton, Hants. [X3859]

**SPARKBROOK**, 1917, 2-stroke, 2-speed, unscratched, just cost £45, indistinguishable from new; £37; extended payments or exchange.—Service Co., 292, High Holborn, London. [X4140]

## Sun.

**SUN-VITESSE**, 2-stroke, 2-speed, new condition, accessories; £30.—87, Buckley Lane, Farnworth, Bolton. [X4045]

**COLMORE Depots**, Birmingham and Manchester, for delivery from stock of all models of Sun motor cycles. [0807]

**SUN-VILLIERS**, late 1915, 2-stroke, excellent order, and a great snip, £17.—Longman Bros., King St., Acton. 'Phone: 1578 Chiswick. [6925]

**SUN-VILLIERS**, 2-speed, new, £37/16; V.T.S. single speed, new, £30/10; extended payments or exchange.—Service Co., 292, High Holborn, London. [X154]

**SUN-VILLIERS**, 2½ h.p., 2-stroke, single gear, new tyres and belt, horn, and lamp, splendid running machine, and enamel and plating in good condition; bargain, £16/10; call evenings.—64, Mill Lane, Brixton Hill. [X4065]

## Sunbeam.

**SUNBEAM Combination**, 1917, 3½ h.p., fully equipped, indistinguishable from new; £105.—Percy and Co., 337, Euston Rd., London. [6939]

**1916 Sunbeam**, 3½ h.p., semi T.T. bars, 3-speed model, hand controlled clutch, kick starter, including all accessories, not done 500 miles; £73.—Box 1,143 c/o The Motor Cycle. [X4090]

**SUNBEAM Combination**, 3½ h.p., late model, with 3 lamps, Lucas horn, speedometer, 35/1 Pillion seat, absolutely as new; £85, no offers.—Short, 485, Upper Richmond Rd., East Sheen. [6670]

**SUNBEAM**, 1914, 3½ h.p., coachbuilt sidcar, Gloria spring wheel, perfect mechanical condition, appearance almost new; £63; any trial; 40 gallons petrol.—Box 1,131, c/o The Motor Cycle. [X3860]

**SUNBEAM**, 1916 (late), 3½ h.p., 3-speed, h.b.c., speedometer, horn, and tools, condition as new; 70 gns.; will take Triumph 3-speed in part.—Hamsterley, 54, Langham Rd., Teddington, Middlesex. [6767]

**1916 Sunbeam**, 3½ h.p., semi T.T. bars, black and gold, 3-speed hand controlled clutch, nearly new, few miles only, perfect condition, with lamps, mechanical horn; £76.—Robinson's Garage, Green St., Cambridge. [6879]

**1917 3 1/2 h.p.** Sunbeam, W.D., green model, in magnificent condition, mileage 350, Lucas lamps, speedometer, Klaxon, A.K. grips, heavy Dunlops unpunctured, exceptionally fine engine; any examination; best offer over £75.—Box L4305, c/o The Motor Cycle. (D) [6917]

**1916 3 1/2 h.p.** Sunbeam Combination, black and gold, 3-speed, hand controlled clutch, Amac carburetter, Lucas horn, Watford speedometer, recently new Bates heavy tyre and tube on driving wheel, and Pedley heavy tyre and tube on sidcar, new Lucas best motor cycle and sidcar lamps, 2 spare valves, and spares, only done 2,400 miles, in excellent condition; 82 gns.—Jarrett, Pharmacist, Trawsfynydd, Merioneth. [X4044]

## T.D.C.

**DE LUXE T.D.C.**, 1916, 2½ h.p.; £23.—W. and H. Motor Co., Ltd., 287, Deansgate, Manchester. [6505]

## Triumph.

**3 1/2 h.p.** Triumph, T.T., waterproof mag., fast machine; £2 £18.—Palmer's Garage, Tooting. [6825]

**1913 Triumph**, 3 speeds, complete, lamps, etc.; £34.—Cross, Eppingham Sq., Rotherham. [X4115]

**1911 Triumph**, clutch model, fine order, lamps; £19.—53, Brownhill Rd., Catford. [6799]

**TRIUMPH**, 1913, clutch model, as new, lamps, horn; £25.—116, Bearton Rd., Hitchin, Herts. [6891]

## IN STOCK TO-DAY.

1917 ENFIELD, 3 h.p., 2-speed 63 Gns

1917 ZENITH GRADUA, twin 75 Gns

1917 ZENITH GRADUA ..... 70 Gns

1917 LEVIS POPULAR, 2-stroke £32 0

1917 ARIEL, 3½ h.p., 3-speed .. £72 0

1917 NEW IMPERIAL-J.A.P.,

kick-starter ..... 46 Gns

1917 NEW IMPERIAL-J.A.P. .. 39 Gns

1917 ROVER and Sidecar ..... £99/4/6

1917 ROVER, 3-speed ..... £77/3/6

1917 ROVER T.T., Philipson .. £65 10

1917 NEW IMPERIAL-J.A.P.,

not done 100 miles .... 35 Gns

1916 NEW IMPERIAL, shop-

soiled ..... 32 Gns

1916 INDIAN, 5-6 h.p., 3-speed 55 Gns

## JULIANS,

84, BROAD ST., READING.

Biggest Light Car and Motor  
Cycle Dealers in the South.

46 years' reputation.

'Phone 1024.

## Used on Aeroplanes, Motor Cycles, and Cars.

**BECAUSE** it's good  
and resists weather  
effects, Robbialac is used  
on speedy machines. If  
your motor cycle is shabby,  
Robbialac enamel will make it  
look new. In tins, 1/6, 2/-,  
4/- (packing and postage 5d.,  
7d., and 8d. extra respectively).  
Robbialac Brush, 1in., 10d.  
(postage 3d. extra).

## Why not Try it?

Sold by Cycle and Motor Dealers.

Sole Manufacturers:

JENSON & NICHOLSON, LTD., LONDON, E.15.

## MOTOR CYCLES FOR SALE.

## Triumph.

**1913 F.E. Triumph**, splendid condition, owner in France; £25. Alfred Drake, Sutton, Ely. [X4006]

**TRIUMPH**, 3½ h.p., 2-speed, and coachbuilt sidcar, wants cylinder; £15.—26, Loxley New Rd., Sheff. field. [X3848]

**TRIUMPH**, 1911, Armstrong 3-speed, coachbuilt sidecar, lamps, etc.; £30.—James, 23, Rosedale Rd., Forest Gate, E. [6910]

**TRIUMPH**, 1909, 3½ h.p., 2 speeds, £19/10; 1911 3½ h.p., spring forks, £22/10.—Motor Exchange, Horton St., Halifax. [6723]

**1914 Triumph**, 4 h.p., 3-speed, lamps, horn, excellent condition; £37/10.—Elce and Co., 15-16, Washopgate Av., Camonile St., E.C. [0552]

**TRIUMPH**, 3½ h.p., weatherproof mag., new tyres, good running order; £10, offers.—Cannon, Yew Tree Cottage, Hayes End, Middlesex. [X4083]

**TRIUMPH**, with sidcar, 3½ h.p., mag., 2 speeds, lamp; £23/10.—Wandsworth Motor Exchange, Ebner St., Wandsworth (Town Station). [6811]

**TRIUMPH**, 1912, 3½ h.p., and sidcar, free engine, all accessories, just thoroughly overhauled; £22/10.—Doughty, 6, Meredith Rd., Clacton-on-Sea. [6899]

**TRIUMPH**, 3½ h.p., 2-speed, F.E., new tyres and tubes, cane sidcar, side door; £22.—G. Applin, 2, Nora Villas, French St., Sunbury, Middlesex. [6830]

**1914 4 1/2 h.p.** Triumph, 3-speed, coachbuilt sidcar, speedometer, lamps, etc., only travelled 1,500 miles; £55.—Procter, Station, Crosshills, Keighley. [X4050]

**TRIUMPH**, 1913, 3-speed, lamps, horn, speedometer, and coachbuilt sidcar, good condition; £35, bargain.—Coles and Soa, 25, St. Barnabas St., Pimlico. [6733]

**TRIUMPH**, 1913, with coachbuilt sidcar, N.S.U. 2-speed gear, free engine, speedometer, perfect condition; £28.—Goddard, 2, Reigate Rd., Ewell, Surrey. [6898]

**TRIUMPH**, late 1913 T.T. model, specially tuned, fast and flexible, economical, excellent condition; £25.—Longman Bros., King St., Acton. 'Phone: 1578 Chiswick. [6924]

**1914 Triumph**, 4 h.p., Sturmer-Archer 3-speed, clutch, with sporting Watsonian coachbuilt sidcar, smart outfit; £49; exchanges.—Newham, 223, Hammersmith Rd., W.6. 'Phone: 80. [6867]

**TRIUMPH**, 1914, 4 h.p., 3-speed, clutch, Lucas lamp set, horn, and speedometer, splendid condition, and Swan coachbuilt sidcar; £42.—Milnes, 12, Radcliffe Av., Harlesden, N.W.10. [X4057]

**TRIUMPH**, 1913, Sturmer-Archer 3 speeds, with 1916 Canoelet Minor sidcar, very little used, new condition, guaranteed perfect; £40; machines only £34.—31, Mount Pleasant, Redditch. [6710]

**TRIUMPH 1914 Coachbuilt Combination**, Sturmer 3-speed, clutch, Bosch, Senspray, Lucas lamps, spares, tyres as new, all in excellent condition; £45.—Sandy, Highland Rd., Aldershot. [6855]

**1913 Clutch Triumph**, in perfect condition throughout, mileage 3,700, trip speedometer, lamps, horn, generator, tyres as new, 2 Dunlop belts, spare valve; £32/10. Wilson, 3, Queen's Av., N.10. [6861]

**TRIUMPH**, 1913, 3½ h.p. T.T., Bosch, very little used, with light basket sidcar, new Dunlop belt, Millers lamps, tyres good condition; £22; seen after 5 p.m.—23, Macleod Buildings, Westminster. [6917]

**3 1/2 h.p.** T.T. Triumph, free engine, clutch, variable pulley, new lamps, tyres, and tubes, link belt Bosch mag., guaranteed perfect condition throughout, splendid appearance, horn, and all accessories; first cheque £27/10 secures.—F. Davy, 61, Edward St., Nelson, Lancs. [X383]

**TRIUMPH**, 1913, 3½ h.p., clutch, Dunlop tyres, enamel plating and plating good, £28/10; 1914, 3-speed clutch, just been renovated by the Triumph Co., complete with sidcar, Covey, P. and H. lamp set, and horn; £45/10; extended payments or exchange.—Service Co., 292, High Holborn, London. [X414]

## Vindeco.

**VINDECO Special**, with coachbuilt sidcar, 5-6 h.p. twin mag., F.E. clutch, wants overhauling; great sacrifice; £13/10.—Wandsworth Motor Exchange, Ebner St. Wandsworth (Town Station). [681]

## Williamson.

**WILLIAMSON** 8 h.p. Combination, w.c. Douglas engine, clutch, kick starter, all spares, (Covey) lamps, complete, splendid condition; £80. Wanted small car.—Rogers, Photographer, Wellingborough. [X400]

## Yale.

**YALE**, 7-9 h.p., 2-speed, 1915, sidcar, accessories; £55.—Fox, Horsley's Garage, York. [X410]

## Zenith.

**£22/10.—3 1/2 h.p.** Zenith Gradua and Sidecar.—Atte 7 p.m., 5, Alexandra Rd., Wimbledon. [680]

**ZENITH**, 6 h.p., 1913 combination, in exceptional nice order; £38.—Percy and Co., 337, Euston Rd., London. [694]

**1915 Zenith**, Gloria coach combination, counterbalance model, speedometer, hood and wind screen, luggage carrier, and spares; £60.—Jewell, 168, Archway Rd., N.6. [682]

**The Petrol Position.**

**I**T is extremely hard to ascertain the real truth as to the petrol position at the present time. On the one hand it is rumoured that there is plenty of petrol in the country, while on the other one frequently sees the statement that the position is critical. It is an open-secret that many ships carrying the precious fuel to these shores have been sunk, but against that fact we have the figures relating to the imports of motor spirit into the British Isles in 1917. We are told that the total imports for the seven months of this year were not very considerably less than those of the first seven months of last year. This is for home consumption only, as it was stated in the House of Commons recently that petrol for the various fronts goes direct to the point of consumption and does not enter this country at all. The result is that there are many hundreds of thousands of gallons of motor spirit unaccounted for, and this after taking into consideration the ever-increasing requirements of the Army and the five per cent. of the total used by the private motorist.

We are approaching, if we have not actually reached, a state of prohibition, having almost attained that point at which motoring for other than purely business purposes is prohibited.

Now the result of this is more serious than is at first supposed. To the majority it seems that, leaving aside the fact that for city people motoring produces health and gives relaxation to a more beneficial degree than most other forms of sports and pastimes, the prevention of it inflicts no more than a slight hardship, which the patriotic ought to suffer patiently; but there is more in it than this. The demand for drivers is still great and is increasing: lady drivers are wanted, and men drivers are wanted, and it is obviously to the advantage of the State that these people, when their services are called upon, should be experienced.

The outcome of this demand has been that nearly all the experienced motorists are now employed in the Government's service, so that

any more who volunteer are inexperienced, or are only partly experienced. What is happening now is that the various motor schools are full up with candidates. A course of motor driving takes six weeks, and although at the end of this period the pupil is usually fit to undergo an examination for proficiency, he or she cannot be said to be so well qualified to take charge of a motor vehicle as one who has owned and driven a motor vehicle for some time.

The same remarks apply to the motor cyclist. The motor cyclist does not go to a school for his training: he learns in the hard school of personal experience, and if the means for teaching himself are denied him he has to undergo his tuition at the hands of the Army—which is the very last thing the Army wants to undertake, as it will be noticed that all demands for motor cyclist recruits specify that the men should have had at least two years' experience.

It is to be feared that a good deal of the outcry against motoring at the present time is due to an anti-motorist feeling among certain sections of the community, and we think that those in authority should bear in mind that the total prohibition of motoring for pleasure will do more harm than good, provided there is enough petrol to go round. If there is not, we ought to be told frankly the position. Nothing would be gained by the enemy if this information were published. Unfortunately, Germany knows pretty accurately the number of tank steamers sunk, just the same as we knew how serious was the petrol position in Germany in 1915, when the Russians occupied all the oil wells which supplied her. Germany, however, was fully alive to her difficulties and prepared to meet them, with the result that home-produced fuel was quickly available and was sufficient for the needs of the Army: we refer to alcohol mixed with benzole.

It is to be hoped that the authorities will take due cognisance of these facts, and seek to encourage, so far as lies in their power, the private owner, and to issue him a little—if only a mere pittance—of petrol.

## Luggage Carrier for B.S.A. Outfit.

A Home-made Spring Carrier at a Cost of Four Shillings.

**A** CHEAPLY-MADE, but at the same time very efficient, luggage carrier has been constructed by the owner of a B.S.A. sidecar, who recently brought it before our notice. The carrier fully answers all requirements in the way of capacity, strength, and freedom from complications, while

Method of fixing the suspension plates to the body of the sidecar.

another good feature is that it can be attached or detached within three minutes.

The platform consists of oak, the two main members being  $2\frac{1}{2}$  in. wide and 1 in. thick, the cross pieces being 1 in.  $\times$   $\frac{3}{4}$  in., bolted together with flush-headed  $\frac{1}{4}$  in. iron bolts.

A point which will appeal to the discriminating motor cyclist is the fact that the carrier is attached to the sidecar body, the result being that it is efficiently sprung and free from the excessive vibration which arises when fixed to the chassis, and this is effected without disfiguring the body.

The rear attachment is made of two pieces of  $\frac{1}{2}$  in. flat iron or steel  $1\frac{1}{2}$  in. wide and shaped as in sketch.

At the back of the body of the sidecar are two plates, each fixed by two bolts, which suspend the body to the springs. The lower bolt on each side is removed, and when the plates on the carrier are registered the bolts are first passed through these and then replaced in their original holes, tightening inside the sidecar.

The other end of the carrier reaches a point well under the sidecar. Holes are drilled through the bottom, also the carrier, and the two bolted together. When fixed up it makes an exceedingly strong and workman-like job, and the writer stood on the attachment and tried to break it, but without effect.

The B.S.A. sidecar fitted with the home-made luggage-grid. An advantage this grid possesses is that it is suspended from the body of the sidecar, thus being insulated against excessive road shocks.

The cost at the outside should not exceed 3s. or 4s. for material.

## A Simple Wick Carburetter.

**W**E have received the accompanying drawing of an interesting wick carburetter from Pioneer Motor Cyclist W. A. Fitch, who has been experimenting with it for the past three years.

Very little description of the instrument is necessary, though we may say for the benefit of the uninitiated that the principle of a wick carburetter is to carburette the fuel by absorbing it in a wick, across which or through which air is drawn at high velocity. Surface vaporisation therefore takes place, and it will be seen that with this type of carburetter there is less likelihood of wastage by drawing a wet, badly carburetted mixture into the engine than with the spray or jet variety. Wick carburetters were used successfully in the early days of car design—the Lanchester being an excellent example of the type—and there are still many engineers who retain the view that, on account of its simplicity and economy, the wick carburetter will yet hold its own against the more mechanical instrument.

The Fitch wick carburetter, the principle of which is described in the text.

The accompanying drawing is, perhaps, self-explanatory. The porous wick, which is easily renewable, is fed from the float chamber, the bottom extremity of it resting, as it were, in a circular bath of petrol. The metal barrel or carburetter body surrounding the wick is freely drilled to admit air, while on the inside of the wick is the throttle piston, which covers or uncovers the wick according to the throttle opening, this regulating the mixture fed to the engine.

It will be observed that the throttle piston is hollow, extra air being drawn through the centre of it, while the extra air holes at the bottom of the carburetter body can be adjusted as to the quantity of air they admit.

Probably this design would be improved if a filter were incorporated to purify the air before it gains the wick—rather than leaving the wick to do the purifying. A fine wire gauze of considerable area, which would also prevent "blow back," could easily be arranged to surround the whole mechanism.

### American v. British Machines.

IT is not particularly graceful to initiate a comparison between our own motor cycles and those of our latest Ally just when our national debt to her is so heavy, but I will endeavour to avoid giving offence by restricting myself to the academic aspects. It is quite easy to see why American and British machines have developed on different lines. In America there were—and are—far more obstacles in the rider's path than in England—steep hills, bad roads, sand, and so forth. Again, our road system was highly developed before the motor era began, and if we preferred, we could always circumvent an obstacle, whereas the American motor cyclist had to surmount it. Until quite recently both industries, and in particular the American industry, relied on single gears. In conquering obstacles one must depend either on high engine power or low engine gearing. The limits of low gearing with a single ratio were tolerably settled by technical considerations, and weight fixed limits to engine power. So America, faced with serious, numerous, and undodgable "obstacles," developed the 7-9 h.p., and we developed the  $3\frac{1}{2}$  h.p. In spite of what 7-9 h.p. enthusiasts may say, the  $3\frac{1}{2}$  h.p. was *not* selected by an arbitrary fiat of the trade, but by a referendum of the general riding public, who made their preferences unmistakable because they dislike unnecessary weight.

### The Advent of Variable Gears.

THE variable gear flooded the U.S.A. market somewhat later than our own, and it offered the American manufacturer his first opportunity of making a choice. It was open to him to begin making a  $3\frac{1}{2}$  h.p. with a low emergency gear, but he elected to carry on with the 7-9 h.p. for a variety of reasons, among which I may mention the following:

- (1.) He knew how to make a good 7-9 h.p., but did not know how to make a good  $3\frac{1}{2}$  h.p.
  - (2.) Sidecars were growing popular, and if we need a big twin for sidecar work on British roads, *a fortiori*, the Yankee rider needs a bigger.
  - (3.) His public were beginning to clamour for certain heavy fittings, especially in the way of increased comfort and lighting installations.
  - (4.) Owing to the badness of American roads, the average American rider belongs by emphasis to the youthful, athletic sportsman type. This type of rider values speed and power more than most things. The British market has long since overflowed this class: the American market has scarcely begun to do so. The American who is getting on in years does not plump for a machine which requires riding and handling, and knowing that most of his jaunts will involve trick stunts through loose sand and among ruts, he goes in for the quantity-produced car in preference to the two or three-track machine.
- For these reasons the American trade was perfectly justified in concentrating upon the 7-9 h.p. class.

### Future Developments.

AFTER road efficiency comes handiness. Therefore the typical American machine will tend to approximate more and more to British patterns, and to grow lighter as American riding conditions improve. For the moment, British machines, as a class, evince retrograde tendencies, for they are becoming heavier. This is due to three main factors, viz., (a) the desire for spring frames, due to the crumbling up of our obsolete road system under stresses which it was never designed to bear; (b) the temporary popularity of the sidecar; (c) the superior attraction of heavy electrical lighting systems over their lighter rivals. This tendency is only an interruption of the lightening process, not its reversal. Other things being equal, the lighter machine will always be the better seller. Indeed, the vast majority of users are ready to compromise and sacrifice other advantages to obtain roadworthy lightness.

### Personalia.

I AM not yet old or lazy enough to put handiness in the absolute forefront. I love speed, I hate road vibration, I loathe engine vibration, and unquestionably a huge twin is attractive on all these counts. It can eat up a road with a minimum of fuss, and it ignores all ordinary hills. As its big engine achieves speed on a high gear and limited throttle opening, it is tolerably devoid of engine vibration, and it laughs at the additional weight of a real spring fork, 3in. tyres, and a couple of cantilevers flanking the rear wheel. But I can secure all my points on certain British machines, which weigh a cool hundredweight less, and therefore my patriotism is hardly appealed to in the matter. If we underline the value of *handiness*, which is the first and last demand of thousands of buyers, the folly of implying that the 7-9 h.p. (British or foreign) stands supreme is evident.

### Light Springing.

LIGHTNESS in connection with an efficient spring frame is probably the chief desideratum of the home market at the present moment, and it will certainly be difficult to encompass and open the door to imported machines. It is not easy to keep a spring frame machine light, and if you dab full springing on a 2 h.p., a  $2\frac{3}{4}$  h.p., or even a  $3\frac{1}{2}$  h.p., you are very liable to rob the machine of its handiness, till it needs treating in much the same tame elephant fashion as a big twin. But no such handicap exists in the case of a monster, which already scales  $3\frac{1}{2}$  cwt. or thereabouts. You always approach it, when it is at rest, in much the same mood as you begin rolling the lawn or shifting the office safe to a new corner, and in neither case does an extra 50 lb. or so matter a tinker's cuss. But if you graft 50 lb. on to a Baby Triumph you spoil it, and that's just going to be the bother for a year or two.

## A Power Unit without Magneto.

A Unique Two-stroke working on the Diesel Principle

SINCE the advent of the Diesel engine, motor cyclists have constantly speculated on the possibility of a power unit on similar lines, by which both the magneto and carburetter could be dispensed with. The advantages of such an engine are obvious on the face of things; not only would the cost of manufacture be very materially reduced, but we should have a unit which, in itself, was the very essence of simplicity.

The unit to be described is the invention of Mr. H. E. Beyer, and though in its present stage it may appear to possess certain defects, there is no doubt that the design contains a germ of possibility in the direction of the simplest type of internal combustion engine. The advantages claimed by the inventor are:

1. Entire absence of any electrical or other ignition device, ignition being effected solely by compression as in the Diesel engine.
2. Means of perfectly regulating fuel and air proportion without the use of a carburetter.
3. Greatly improved scavenging; the power cylinder scavenged by air only, eliminating wastage of petrol through the exhaust ports and by condensation. The volume of air used for scavenging cylinder is in excess of the working volume of the cylinder, so that a quantity of air is allowed to pass with each stroke through the exhaust port; the fuel not being admitted until the piston nears the top of the compression stroke.
4. Increased efficiency owing to higher compression.
5. Cheapness of manufacture.
6. Satisfactory for using paraffin, petrol, benzole, or alcohol.
7. Reliability owing to absence of ignition device.

### How the Engine Works.

The engine illustrated consists of a single power cylinder and a fuel compression cylinder; gaseified fuel is admitted to the latter, while air only is admitted to the power cylinder by the transfer port.

know it, and also the magneto. The small drawing shows the float chamber with flash tube passing through the exhaust to the compression cylinder.

The expulsion of exhaust gases and the inlet of the new charge of air are effected in the usual way. It will be noted that the power and compression pistons are at the bottom of the stroke at the same time, thus a larger quantity of air is drawn into the crank case than in ordinary practice, for on the upward stroke a charge is drawn into the crank case equivalent to the displacement of both pistons, while on the downward stroke this increased volume of air is forced into the power cylinder, a portion of it (theoretically equivalent to the displacement of the pumping piston) overflowing at the exhaust.

Let us follow now the working of the engine. As the power piston nears the bottom of the power stroke, the highly compressed air in the crank case sweeps into the cylinder, forcing out the burnt gases at high velocity. At the same instant a jet of gaseous fuel, flashed into vapour by the heat of the exhaust, is drawn into the compression cylinder, which begins to move upwards in unison with the power cylinder. As the air port of the power cylinder is closed, simultaneously the fuel port in the compression cylinder is closed. Both pistons move upwards in unison, the power cylinder compressing pure air, the compression cylinder compressing pure gas. As the compression cylinder reaches the top of its stroke it automatically taps open the valve interconnecting the two cylinders, thus allowing the gas at exceedingly high pressure to join the compressed air in the combustion head of the power cylinder.

It will be seen from the drawing that the pure fuel gas in the compression cylinder is compressed to a much higher pressure than the air in the power cylinder, otherwise it would not pass into the latter. The compression of both cylinders is so high as to cause instantaneous combustion as the inflammable gas meets the compressed air in the combustion space.

On the downward stroke—the power stroke—a vacuum is caused in the compression cylinder.

**A Power Unit without Magneto.—**

der, and at the bottom of the stroke the gaseous fuel is admitted to this vacuum. Vaporisation, be it noted, is assured not only by the introduction of the spray into a vacuum, but by the heat of the tube in which the fuel is sprayed—this tube passing through the exhaust pipe at its hottest point.

**Pressure and Ignition.**

Automobile compression pressures have always been governed by the fact that beyond a pressure of approximately 120 lb. per square inch, petrol or paraffin gas when mixed with air will cause pre-ignition. The engine under review is designed to obtain a pressure of 150 lb. per square inch maximum in the power cylinder, and 250 lb. per square inch in the compression cylinder. The proportion of fuel and air, and also the regulation of the engine, are effected by means of a throttle valve in the gaseous fuel pipe, and by means of a throttle valve in the air supply port to the crank case. It is claimed that the pressure in the compression cylinder being so high, the act of throttling down will not sufficiently reduce the pressure to cause defective running. Taking, say, petrol as fuel, the usual proportions worked to are one of petrol to eight hundred parts of air, measured by volume. Taking the gaseous fuel on admission to the compression cylinder at 120° Fahr., and at slightly below atmospheric pressure, and the air at normal temperature and pressure, the proportion of fuel to air by volume is 1 lb. to 42 lbs. With this it is conceivable that the compression cylinder used, although small, is adequate.

**A Fixed Ignition Engine.**

It would seem with this type of engine the chief difficulty would lie in starting, though the inventor claims that no great difficulties are anticipated in this direction. He points out that in the down stroke of the compression piston the lift of the small valve is so slight that only a negligible quantity of gas is retained in the pumping cylinder. This quantity, he claims, is sufficient, when the engine is cold at starting, to carry the fuel as vapour for the first power stroke, the exhaust from which immediately assists in vaporisation; thus no special provision has been made for gasifying fuel for the first stroke.

It will be noted that no allowance is made for varying the point of ignition. A decompressor has not been shown, but this would be added to a motor cycle engine. It may be added that a single-cylinder engine on the lines described will very shortly be completed, and the results of a trial will be available.

(Left) Sectional drawing of the Beyer engine.  
(Right) Section of pumping cylinder in which the gas is compressed before entering the power cylinder.

**DR. LOWE'S CRITICISM.**

The design is by no means novel; it simply consists of a slightly different method of using a pump cylinder of sufficiently high compression to ignite the charge by its own heat when injected into the air. If to control the engine this pump pressure is reduced, it is not really accurate to say, as is claimed, that the combined temperatures would be enough to ignite the charge, because the expansion of fuel vapour into the working cylinder will naturally reduce its temperature rapidly; the ignition will be extremely rapid if it is to be effective, and as the fuel is in the form of a liquid the rising pressure would probably be more rapid than that of the Diesel engine, necessitating very heavy parts indeed. It may be pointed out that, although it

would probably be extremely efficient as regards petrol consumption, efficiency for motor work must be considered as all-round efficiency; a method of timing the ignition is, therefore, absolutely necessary.

It must not be forgotten that only a certain amount of petrol can be consumed, and as there are no means of obtaining the ignition temperature the engine would be very uncontrollable, and would probably only be controllable at one speed, during which time it would be efficient as regards consumption only. The gas must come in nearly all at once to obtain quick ignition in this system; the pressure will rise almost instantly, giving a very uncontrollable engine, and if the engine were very much throttled down in the manner suggested it is possible that, unless the compression were excessively high, the temperature might be sufficiently reduced to prevent ignition, and in this connection the addition of a small igniting apparatus or direct mixing apparatus for the air and petrol would be an improvement.

**The Value of the Principle.**

The fact that the invention is not novel does not detract in any way from its cleverness, which is undoubted, or from the value of the principle, which, under many other patents covering the past thirty years, will undoubtedly supplant the carburetter in years to come.

As far as using other fuels is concerned, it must be remembered that the temperature is varying with the compression, and therefore cracking will take place in different degrees, leaving, for example, the whole of the tarry and pitchy matter in the delicate pump cylinder. As far as its thermal analysis is concerned, the engine is largely comparable to a hot bulb semi-Diesel two-stroke.

# ROAD TEST OF NORTON EMPIRE MODEL.

Practical Road Notes by a Practical Rider.

**W**E were told that every machine in the crowded ranks of the Norton finishing shops was up to a certain standard, and in support of this statement we were invited to visit the works at any such time as our fancy dictated—"Pick any machine from the rank, push it to the door, give the kick-starter a dig, and away you go two or three hundred miles as you choose, subjecting the machine to any fair test you can think of."

This is the sort of sporting offer one does not like to turn down, and accordingly one stormy July evening we strolled into the Norton factory, selected the last machine in the last rank, and ten minutes later were threading our way down the dense and erratic traffic of Bull Ring.

It may be mentioned, *en passant*, that that glib sentence about "give the kick-starter a dig and away you go" did not pan out just in text book order. Those whose riding is mainly confined to the use of "small twins" may lose the art, or they may fail to develop those partial biceps necessary for boosting round a hefty single. At all events it required more than one rather feeble effort ere we were greeted by the good old Norton bark, and we would suggest that some ever ready primary device—quite apart from the pilot—would be appreciated by the aged and weak-kneed.

The model which is here to be discussed is the Norton Empire model—the machine built for the military requirements of to-day and the Overseas rider of to-morrow—the Norton 4 h.p. all-chain (totally enclosed) big single. It is in every respect cut out for strenuous and unsparing use—a rough country, go anywhere, double-purpose machine of absolute reliability. It is not designed for speed, but both in power and strength of design a wide margin is left for the most extreme conditions, and during the comparatively short period the machine was in our hands we were able to form the opinion that no amount of deep sand or merciless mud-plugging—real mud-plugging—would cause this very practical mount to fall off in power. Let it be quite clear, then, that the following notes do not refer to the  $3\frac{1}{2}$  h.p. speed model Norton. Be it further understood that by the employment of higher gear ratios, this mount would make an ideal solus for those who love a "single" capable of taking a really high high gear.

The machine we rode will probably be ploughing its way, in a month or two, through the axle deep mud of the Eastern front, handled by a clumsy rider, and the gear ratio being decided for such work, it is only natural that, on our smooth highways, it seemed absurdly low geared, considering the abnormal kick of the engine. Given a 4 to 1 gear and judicious finger-

ing of the clutch, very short shift could have been made of the long level stretches, for the engine proved capable of attaining and maintaining a high rate of revolutions. In traffic the manner in which it would tick over on top gear, the clutch slightly eased, was distinctly pleasing, while naturally it proved capable of quite unusual acceleration—an ideal traffic machine.

## Comfort and Reliability.

A fair mileage was covered on ordinary business rounds, during which we were able to sum up the general qualities of the Norton. As regards the all-chain drive, no necessity was felt for a friction shock-absorber except when bad riding was indulged in. If the clutch caught up unexpectedly at low speeds, if the mixture or the gears were muddled, then a distinct snatch in the solid drive was experienced, but owing to the heavy flywheels and the low compression no harshness was detected at any other period. It may be added that the riding position was most comfortable and the control excellent, though the incorporation of a half-compression device in the valve timing mechanism is, we consider, a necessity. We can picture the uninitiated Cossack attempting to start this mammoth amidst the Russian snows with the temperature hovering about the zero point and the roads heavy with snow or glassy with ice.

During the preliminary tests the petrol consumption worked out at approximately 65 m.p.g. on short journeys, with much traffic riding and stopping and starting work. This would probably approximate 80 m.p.g. straight riding, and the jet was decidedly on the large side.

## A Hill-climbing Test.

Stoneleigh is not much of a test for such a machine, but thither the Norton was ridden to be put through

The 4 h.p. ( $82 \times 120 = 633$  c.c.) Empire Norton under test. This model was fully described in the November 30th issue of *The Motor Cycle*, and is identical with those built to the Russian Government's order.

**Road Test of the Norton Empire Model.—**

its paces accompanied by a flat twin designed somewhat for speed. On its top gear of 4.96 to 1 the Norton proved capable of 45 m.p.h. all out, and its most noticeable period of vibration was between 32 and 37 m.p.h. If at these speeds the throttle were closed or partly closed the vibration was very noticeably increased—points which were due to the unnecessarily low gear, which enabled the big engine to “over-run” itself. With a family sidecar attached, two tins of petrol, luggage, etc., on the grid, and a lusty ten year old youngster on the carrier, the gears would have been about right, but ridden solo the machine was seen at its worst. Suitably geared a speed of well over the fifty mark would have been easily obtainable.

**The Norton as a Hill-climber.**

Stoneleigh was taken without any opening of the throttle and without falling off in speed. On its present gear a sidecar of normal weight with passenger would make no perceptible difference to the speed capabilities of this mount.

As a speed test the hill with its maximum gradient of 1 in 9 is too short and insufficiently steep to be of value in testing such a machine. The Norton, on its top gear, would ascend at a crawl on the merest whiff of petrol, whilst at the slightest opening of the throttle it proved capable of instant acceleration on the steepest portion and without the least suggestion of knocking or labouring. Later the machine was driven all out for several miles, run for some minutes at the foot of the hill with magneto retarded and engine free, jerked into top gear, and subjected to yet another slow climbing test which it performed without

knock or suggestion of heating. The hill for the first eighty yards was ascended on top at about 8 m.p.h., then the throttle was thrown open, whereupon the engine picked up cheerfully, as though fresh from the garage doors.

**An Ideal Overseas Mount.**

Meeting a group of Triumph testers on the top of Stoneleigh, the men were much interested in the Norton, and running comparisons between the two well-known makes—favourable and the reverse to both—prevailed. We enquired of the testers if they knew of a worse gradient—something really tricky—and were referred to the bank which rises almost perpendicularly for twenty-five feet or more from the roadside at the hill top. This murderous little ascent, with its wooden palings at the top, has more than once been tackled by Triumph testers, but as we were desirous of returning the Norton to the factory in something like the condition we found it, the experiment was not attempted.

Finally, it may be added that we consider this machine in every way suitable for Overseas requirements. The unusually liberal ground clearance, all chain drive with excellent enclosing cases, and the steady pulling, untirable engine render it specially adapted to the hardships of pioneer roads. The machine throughout is extremely strong, mudguard clearance is good, and it is particularly suitable for double-purpose requirements, the hard pulling of the engine at low speeds being remarkable. It is unnecessary to add that the fittings and the design throughout are excellent, and that a ready market will await this serviceable mount cannot be doubted.

## AN EARLY SPRING FRAME.

**A Practical Design of Ten Years Ago.**

THE accompanying photograph of the spring frame Bat motor cycle, which made its appearance some time prior to 1907, was unearthed by the proprietor of Maude's Motor Mart when looking through some old papers a short time ago.

It will be observed that the springing, though ingenious, lacks many of the features which are considered absolutely essential in these days of spring frame design. How the vertical rigidity of the front wheel is retained it is difficult to gather, nor is it easy to decide from a study of the photograph exactly how the rear springing mechanism operates. Apparently the spindle of the wheel and the U piece passing over the wheel com-

prised the unsprung portion of the frame, two vertical coil springs, which occupy their perilous positions on either side of the wheel, insulating this unsprung portion from the rest of the frame.

In writing to us regarding the invention, Mr.

George Pettit states that he does not submit the photograph as a model of elegance, but that at the same time he can vouch for its comfort, apart altogether from its tendency towards side-slip on wet roads due to the lack of lateral rigidity in both wheels. The machine certainly does not appeal to one as a type for negotiating greasy roads.

A very early spring frame Bat. Though curious in appearance it was comfortable riding. Its fault, as may be imagined, was a tendency to side-slip on grease.

# A NOVEL FOUR-CYLINDER LAYOUT.

## A French Reader's Unobtainable Ideal.

THE illustrations appearing on this page show an attractive design of four-cylinder machine, the work of a French reader, M. Henri Boursiac, who writes us that this is his ideal type of mount, but one which, like many ideals, is unobtainable. The general layout of the machine is certainly very taking, and many of the points of design are distinctly ingenious. The specification is as follows:

The engine is a four-cylinder two-stroke with the gear box cast in unit with the crank case. The cylinders are air-cooled and enclosed by an artistically-lined shield or cowl, which protects the rider's legs from heat and spray. At the end of this cowl, facing forwards, a four-bladed fan is placed, this being positively driven from the engine, and so arranged that a powerful current of air is carried through the enclosing shield. The cylinders are cast in pairs, only one detachable head for each pair; thus the simplicity and accessibility of a twin-cylinder engine is obtained. M. Boursiac suggests an automatic one-lever carburetter and a magneto-dynamo for ignition and lighting.

The bonnet and the four-bladed fan fitted to assist engine cooling.

The frame design appears to be excellent. It will be observed that the engine is slung in a cradle, the

frame being duplex from the middle tube downwards. It is sprung fore and aft. The rear springing, though not remarkable for novelty of conception, appears to promise a fair degree of rigidity, and the comfort of

A design for a four-cylinder motor cycle submitted by a French reader. It has many attractive features, and the layout is decidedly pleasing.

the rider is added to by a new type of cantilever saddle supported by one enclosed coil spring. The front springing is certainly interesting, and though at first glance reminiscent of the Triumph system, the distribution of the springs is differently arranged.

Long coil springs, contained in dust-proof and grease-packed cases, are used, and the design, though clever, appears somewhat experimental. Three speeds, of course, are provided, the clutch being of the dry plate variety, easily adjustable, and foot and handle-bar controlled. The helical drive to the rear wheel is entirely enclosed, the universal joint being in a gritproof case. M. Boursiac plumps for 28in. x 2 3/4 in. tyres. The semi-T.T. bars are adjustable; the carburetter and magneto controlled by twist grips, thus reducing the number of handle-bar levers. Pressed steel folding footboards are suggested, both brakes operating on the rear wheel. No doubt this clever design will tempt other readers to advance their views as concerns the ideal post-war mount.

A pair of cylinders cast in one piece with only one detachable head for the two.

## Reliability Trial in South Australia.

THE annual reliability trial of the Motor Cycle Club of South Australia was held on 2nd and 4th June over a distance of 240 miles. The first half-day's run was over good roads and in fine weather. The second day, however, was wet, and part of the distance being over unmade roads the riders had a sample of riding under the most strenuous winter conditions. Besides points being lost for breakages, one point was deducted for every fifteen seconds early or late at each control, of which there were seven, two of them being secret. The results were as follow:

1. A. N. Smith (Harley-Davidson sc.) .....	points lost	27
2. J. R. Day (Harley-Davidson sc.) .....	"	87
3. V. P. Elliott (Elliott two-stroke) .....	"	100
4. R. Brown (B.S.A. sc.) .....	"	110

5. H. Warren (Lewis two-stroke) .....	points lost	298
6. H. C. Rainsford (Indian sc.) .....	"	424
7. C. W. A. Korner (Indian) .....	"	592
8. J. Smith (Harley-Davidson) .....	"	677
9. L. Benisch (New Hudson sc.) .....	"	864

C. S. Lindsay (Douglas), C. Lindsay (Lewis), W. H. Hubbard (J.A.P. sc.), L. R. Buckeridge (Indian sc.), F. W. Cook (Indian sc.), H. U. Johnson (Hazelwood sc.), G. F. Hayes (Harley-Davidson sc.), and E. Ferguson (Indian) retired at various stages of the contest.

### GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD.

## OVERSEAS SECTION.

A Commentary based upon Practical Experience and a Study of Overseas Opinions.

### Universal Petrol Scarcity.

THE petrol scarcity promises to become universal. Recent news from America signifies this, and if America becomes short of petrol a goodly portion of the world will suffer the same irritating and irksome restriction. We, in England, have learnt to eke out our slender supplies in various ways, and the everyday motor cyclist who must remain on the road has been called upon to think of the best ways and means by which this tiresome performance can be accomplished.

During these times, when sacrifice and privation are the daily order for so many, it ill behoves us who are privileged to remain quietly at home to complain simply because the open road is not quite so open as it used to be. It remains with us to carry on as best we can. All we ask is a straight story and the fulfilment of promises; but we would point out that, in these days when the future is a matter of lurid haze, those who are to decide the petrol question in the domains of the Allies Overseas would do well to avoid promises or anything that might possibly be misconstrued as such. In Britain we have already seen that anything in the way of a promise may cause the truly patriotic to suffer, while those who have few scruples suffer least. The future is not in the hands of any one tribunal, therefore promises are a matter of speculation.

### The Question of Cubic Capacity.

RIDERS who are unacquainted with the general order of things in our Overseas Dominions express wonder that big engines enjoy such popularity in those regions. We have our small, highly-efficient engines which, on our roads, give unqualified satisfaction, and the opinion of the average British rider is that they would fill the bill equally well for the man Overseas. But not only are the conditions of riding vastly different in our Dominions, but the light in which the pastime is viewed is equally distinct. The Overseas rider does not want a small "revving" engine—not so much on account of its low power, but on account of its lack of stamina. He demands an engine which, after four months of rackèet and bad handling, will still carry him through—an engine which, though it lose 50% of its tune, is still good for a speed burst, which is only limited by the condition of the road surface encountered, and which, after months of hard slogging, retains its tune sufficiently to meet his daily requirements.

The majority of riders Overseas regard their machines purely as business propositions, and the universal mount should be one which is in no way dependent

on decent tuning, but which can be depended upon to slog away with an adequate reserve of power for long periods at a stretch. These salient features can only be obtained on the large, low compression, side-by-side valve engine which is running constantly on top of its load.

### The Efficient Flat Twin for Overseas.

IT is an open question as to whether the overhead valve, highly efficient, high-speed engine is suited to the requirements of those whose riding is chiefly over rough country. As regards reliability, this type of engine—it being taken that we refer to the overhead valve flat twin—leaves little to be desired, though it certainly requires more adjustment and demands more delicate handling than the low compression touring engine. It is also more particular as to the plugs it uses; and while with an ordinary touring mount one never gives a thought to these important members, one very soon begins to learn things about plugs with the high speed engine. The valves, too, require watching for adjustment, but quite apart from the matter of hardness, the efficient flat twin machine is seldom so easy to handle as the side-by-side valve variety. The main ambition of this type of engine appears to be the accomplishment of most astounding "revs." It will not tick over on full load for long periods at a stretch, as an Overseas mount *should* do. Under such treatment it appears to become irritable, and a shade unmanageable and harsh. To put the matter in a nutshell, this type of engine is a delightful proposition on roads where the rider is able to "keep up the revs," change early, and has not constantly to pick his way; but when the going is difficult the successful riding of such a machine demands constant twiddling of the levers and very delicate manipulation of the clutch; *i.e.*, skilled driving. In this country it is a mount for the skilled rider *only*, and Overseas it would be very much more so.

### The Side-by-side Flat Twin.

THE above remarks apply only to the overhead valve flat twin, and do not bear in the least on flat twins as a whole. If we are content with two cylinders the flat twin will undoubtedly supersede the V twin on account of its superior balance and torque, and because it is in every way superior as an engineering proposition. And so, though the highly efficient variety with overhead valves is not particularly cut out for rough country work, we shall undoubtedly see the big engined side-by-side valve, low compression type of horizontally opposed enjoying wide popularity as a universal mount ere many years are out.

## A Selection of Letters from Readers scattered all over the World.

### Control Levers.

O. VIAZEMSKY, Petrograd, writes: "Being in need of a new carburetter control for my motor cycle, and not being able to purchase one, I decided to make one myself."

"As the roads out here, even main ones, are now in an appalling condition, owing to war traffic, ordinary control levers are not at all satisfactory, as the levers themselves are very stiff, and are fitted with hard little knobs at the ends, which very soon numb one's fingers and ruin the stoutest of gloves. So I made mine out of  $\frac{1}{8}$  in. spring steel, about  $\frac{3}{4}$  in. wide, tapering a little towards the ends. To these I fitted little padded cushions, made out of an old glove finger filled with insulating tape (rubber would do very well).

"The result was quite an eye-opener, and now I am able to adjust my engine to all the variations of the road surface without being at all inconvenienced by the vibration, as the levers themselves perform the duty of shock absorbers. I wish *The Motor Cycle* every success."

[Had our correspondent fitted weaker return springs to the carburetter pistons he would probably have experienced no stiffness in the working of his levers—taking it, of course, that the pressure on the friction plates was correct, and the wires working freely.—Ed.]

### Advantages of a Governor Pulley.

From "JIMBILL," Adelaide, South Australia: "I climbed across my first motor bicycle in 1903. It was a 2 h.p. Minerva (clamped to the down tube), and was a dinkum engine (still running). I remember the controversy anent the a.o.i.v. and the m.o.v., when Mr. Wells—who was then a Vindec man, I think—said he preferred the a.o.i.v. to the side-by-side m.o.v. I wondered if he got 'borak' poked at him when the Indian changed the position of its intake? I also remember Brice and 'The Brown' when they thought he used picric acid. It is a queer thing, I always associate 'Ixion' with Brice; I (without reason) thought them one and the same man. There are many things I could write about, I reckon, but with the war on a man dislikes to do so; but I just want to ask, concerning the ink spilling over the merits of the baby and the flat buzz-waggon as against the  $3\frac{1}{2}$  h.p. single, has anyone ever ridden a  $3\frac{1}{2}$  h.p. with only a frame and a pair of wheels, so to speak, driven from a Philipson pulley geared  $4\frac{1}{2}$  to 1? This is my mount, and 'Ixion' can have all his 'grids' that want special plugs, etc. Will 'Ixion' take his  $3\frac{1}{2}$  h.p. fixed engine, have a good run, come back, and attach a Philipson pulley, and then go out again? I am thinking he will not be so keen on his buzz-waggon afterwards. I am not keen on testimonials, believing in getting value for my money, but this pulley makes as much difference to the 'kick' of a motor as the British Empire makes to this war. The Philipson pulley does all that is claimed for it and more; I have proved that belts and tyres last longer with it, as do the bearings of the engine. I use a  $3\frac{1}{2}$  h.p. King Dick, Sun fittings, and it surely can skip. Here's handing you a bunch of flowers for the way in which you have run the paper through this disturbance; I take it regularly. Hooray for the bull-dog breed!"

### An Overheated Carburetter.

C. S. SAUNDERS, Calcutta, writes: "The following experience may prove interesting, and I hope useful, to some of your readers in the Colonies where the temperature in the shade goes up to 115° or above."

"Eighteen months ago I bought a second-hand 1913  $3\frac{1}{2}$  h.p. Triumph with three-speed S.A. hub gear. Not being satisfied with the consumption obtained by the standard carburetter, I purchased a 1915 model 3 jet Binks carburetter."

"The result riding solo was delightful, giving wonderful flexibility, speed, power, and low consumption. I rode the machine solo for a few months, and then put on a canoe-shaped wicker sidecar. Then the fun began!"

"The outfit would run splendidly for a mile, after which a mysterious misfiring began. The machine would miss once or twice, then go for a quarter of a mile or less, sometimes even more, firing regularly, then the same trouble recurred. This went on regularly, and there was a great falling off in power."

"I must here state that I am an engineer, and have made motor cycles and cars my hobby for the last thirteen years, so I am not a novice; moreover, I do all my own repairs, such as rebushing."

"Everything was tried, all combinations of jets, lowering the compression, all the best types of plugs, lowering the gear, and the engine thoroughly overhauled. The valves were perfectly free and correctly adjusted—ignition perfect."

"No one was able to solve the problem, and I was just going to sell the machine in disgust, when I noticed one day, having stopped after a run of ten miles, that there was a peculiar gurgling noise going on in the carburetter. I took off the gauze cover and opened the throttle wide, and saw that the petrol was boiling in the float chamber and spurting spasmodically from all three jets. As you know, the carburetter stub is a very short one, therefore the carburetter is close up to the cylinder."

"As a last resort I had a pipe made,  $5\frac{1}{2}$  in. long and 1 in. diameter, which I turned down on the inside to fit the stub, a driving fit being allowed. I also turned down the carburetter end of the pipe to fit the carburetter properly. I moved the oil gun round on the down tube to make room for the float chamber, and then, having fixed everything properly, I started up. The result was magical. All bubbling stopped, the carburetter only became slightly warm after running all out at 45 m.p.h., with sidecar attached and a total weight of 24 stone passenger load. The machine would cut down on top gear without snatching to seven miles an hour (the gear being  $5\frac{1}{2}$  to 1), and the petrol consumption, with the shade temperature at 103°, with sidecar and 24 stone passenger load, keeping up an average of 21 m.p.h., often against a head wind, worked out consistently to 80 miles per gallon. The jets were Nos. 0, 4, and 10. The machine romped up grades of 1 in 10 at 20 m.p.h. on top gear with the throttle only half open, and would do 45 m.p.h. with ease. There was no overheating, and the engine ran like a 6 h.p. twin."

"This is a true yarn, and as I had so much trouble and only solved the problem by accident, I think it is worth recording. This proves that a long inlet pipe, which, by the way, keeps very hot, coupled with a cool carburetter, is the ideal condition for power, flexibility, and good petrol consumption."

"Before closing I wish to say that I have learnt no end from your paper, which I have taken in since 1904, and always look forward to mail day when the English papers arrive."

AMERICAN ARMY IN FRANCE.

The United States motor transport service has been at work some time in the French lines. The drivers are almost all graduates of the Cornell University. The photograph shows the American motor transport waggonettes and American Motor Scouts now at work on the French front.

# Road Demonstration of Tilston Two-stroke.

A Meeting of Well-known Engineers and Interesting Discussions on an Unusual Phase of the Two-stroke Problem.

IT was quite like old times to be present once more at a gathering at which the faces of well-known engineers and erstwhile competition riders were present. The area opposite that popular rendezvous of pre-war motor cyclists—Stonebridge Hotel, between Birmingham and Coventry—certainly did not suggest the conditions of a petrol famine. On the day of demonstration it was occupied by a variety of machines ranging from the two-stroke lightweight to huge Cadillac and Daimler touring cars. The owners of these cars and cycles were men who had stolen a brief respite from what may be described as among the most trying labours of the war—that of the munition worker—men who, casting aside the old conservatism that once hampered our industry, were there to investigate the fruits of another man's labours, which, let us hope, will tend towards the advancement of what has now proved itself to be a potent factor in the strength of a nation's arms.

Mr. Tilston's genial invitation to lunch with him and to "see for ourselves" resulted in an excellent representation of the motor trade, especially that section of it concerned in the development of the two-stroke, such firms as the Triumph, Levis, Sun-Vitesse, Sunbeam, and Lea-Francis being represented, while among the motor cycles of interest was to be observed the new chain-driven Triumph, and (not a word) a spring frame Sunbeam (still in its experimental stage). After lunch Mr. Tilston produced working models of his piston valve engines, and though the chief object of the meeting was the demonstration of the piston valve two-stroke, a proposed four-stroke design working on similar lines was also brought forward. As the principle of Mr. Tilston's invention is probably little known, it will be as well to describe briefly the fundamental working principles of these

engines, which will appeal as entirely new to the majority of our readers.

## Description of Two-stroke Engine.

Taking, firstly, the two-stroke. In this engine a vertical valve cylinder of approximately half the bore and half the stroke of the working cylinder, occupies its place alongside the latter.

With the engine rotating the piston valve works in exact unison with the power piston, and is operated by means of a plain bearing cam on the crankshaft. At the top of this auxiliary cylinder is a port which communicates from the combustion head on one side and the exhaust on the other, while at the bottom of the working cylinder is an ordinary transfer port from the crank case.

Diagrammatical section of the Tilston two-stroke engine.

Mr. Tilston is aiming at high volumetric efficiency and improved internal cooling. This, he argues, cannot be obtained when the inlet port and the exhaust ports are opposite each other, as in ordinary practice. He asserts the view—with which we do not necessarily agree—that the deflector on the piston head of the present-day two-stroke accomplishes its object only in a half-hearted manner; that, in spite of drawing board arguments, a great deal of good gas is swept out of the exhaust while a great deal of bad gas remains in the cylinder to be compressed—hence, high fuel consumption and four-stroking at low speeds. Thus, the volumetric efficiency of the present-day two-stroke is inevitably low. The volume of gas forced into the cylinder can, at the best, only be equivalent to the displacement of the working piston on its down stroke, so that a volume of bad gas theoretically equivalent to the capacity of the combustion head must remain in the cylinder after the period of exhaust. In the design of engine under review, however, the volume of gas swept into the cylinder is equivalent to the displacement of both the working piston and the valve piston, while scavenging is rendered efficient by reason of the fact that the fresh charge is forced in at the bottom of the cylinder while the exhaust is forced out at the top and at the other side of the cylinder, the top of the piston being flat so that the gases rush in and pass out without impediment of any sort. Immediately the piston starts on its upward stroke the piston valve closes, thus preventing overflow of the fresh gas from the exhaust port.

## An Internally-cooled Four-stroke.

So much for the inventor's expressed views as concerns the two-stroke. An idea of the four-stroke engine can best be obtained from the accompanying illustra-

Piston valve side of the Tilston power unit. Note the cap for withdrawing the gudgeon pin of piston valve.

## Road Demonstration of the Tilston Two-stroke.—

tions. On paper, this engine possesses unique possibilities. Firstly, the carburetter induction is opened up on a vacuum—i.e., when the piston has accomplished the greater portion of its down stroke, so that induction is effected by what can best be described as a "snatch" on the carburetter. Secondly, this engine—which is as yet a paper proposition—promises an efficient system of internal cooling: a matter which

as regards cool running in his engine by the effect not only of scavenging the cylinder internally with cold air, but further of cooling the piston inside and out, and he considers that, owing to this unique feature, air-cooled engines of very large size could be built for car use on the lines of his invention.

## Piston Rings and—a Challenge.

Mr. Tilston had some remarks on the apparent uselessness of piston rings, and on the valve pistons here described he has abandoned the use of rings. He suggested that some engineer present who had shops at his disposal might experiment with scientifically-constructed engines having no piston rings. He argued that, while rings are indisputably necessary in engines having a bore of, say, 24in. or thereabouts, the loss past the piston is so small during the minute interval of compression of a high-speed small-bore motor cycle engine that it could advantageously be ignored when reliability and simplicity are involved. We would point out, however, that the loss remains proportionately the same, whatever the size of the engine may be, and that in the case of a small bore engine a minute loss is very much more significant than in the case of a large engine. Further, an internal-combustion engine is so much of a compromise that it has been definitely proved that the point of over-scavenging can be very easily reached. This Mr. A.

G. Cocks (Clyno Co.) pointed out; the small amount of burnt gas remaining over from the exhaust period has the effect of warming the fresh charge, thereby preventing instant condensation on the cylinder walls, and, further, it has the effect of deadening the force of the explosion sufficiently to sweeten the running of the engine. We are inclined, therefore, towards the view held by Mr. Cocks that the engine just described may prove in practice to be a trifle over-scavenged, but its cool running is undoubtable.

Naturally, Mr. Tilston's views were contested by prominent trade members present, most of whom,

## THE TILSTON FOUR-STROKE PISTON VALVE ENGINE.

Fig. 1.—Commencement of power stroke; pistons descending; all ports closed.

Fig. 2.—Exhaust stroke; piston valve has uncovered exhaust port; compressed air from crank case being transferred to cylinder.

Fig. 3.—Beginning of vacuum stroke; exhaust port closed; working piston descending.

Fig. 4.—End of vacuum stroke; inrush of gas from carburetter and transfer of compressed air from crank case.

for some little time past has occupied the thoughts of many of our readers. At the bottom of the cylinder there exists a transfer port communicating with the inside of the crank case, as in ordinary two-stroke practice, and pure air compressed in the crank case is used to scavenge the engine during the exhaust stroke.

The piston valve is, of course, driven at half engine speed, and let us now follow the cycles of operation. On induction the piston travels almost to the bottom of the stroke with all valves closed. At this juncture the bottom of the piston valve uncovers the carburetter port, and the gas is drawn at high velocity direct from the carburetter into the cylinder. An interval later the power piston, now nearing the bottom of its stroke, uncovers the transfer port from the crank case, thereby admitting a blast of cold air to the cylinder (this, it seems to us, would cause blow-back from the carburetter, but the inventor claims that the interval during which both ports are open together is only sufficient to relieve the vacuum in the cylinder). Compression and expansion follow in the usual way, but at the bottom of the power stroke not only is the burnt gas allowed to escape into the exhaust by the opening of the exhaust port by the valve piston, but scavenging is further assisted by the inrush of cold air from the crank case *via* the transfer port at the bottom of the power cylinder. This, claims the inventor, displaces the burnt gas which, being equivalent to the unswept area of the combustion head, remains in the cylinder in present-day practice, and he argues further that the negative work done in working poppet valves is greater than the negative work done in working the valve piston, while in his design wear and noise are very much reduced. He also points out the enormous advantage

Mr. Tilston, the patentee, conversing with *The Motor Cycle* representative outside Stonebridge Hotel. The engine, it will be seen, is fitted into the frame of a Baby Triumph.

## Road Demonstration of Tilston Two-stroke.—

however, admitted that they were deeply interested. Mr. Cocks challenged Mr. Tilston to run his machine over a route (to be chosen by Mr. Cocks) in competition with a standard two-stroke conforming with present-day ideas. Mr. Tilston replied that if any manufacturer present would undertake to build his engine at a stated figure he would then be in a better position to consider challenges. He had experimented and built his present model at enormous cost and under great difficulties. It consisted of the remnants of a Baby Triumph adapted in the best way possible under prevailing difficulties. It was not a fair representation of his invention, as he lacked the facilities to build and experiment. The machine that was to be demonstrated was merely a "botched up affair," and therefore those present would realise why he could not accept challenges from manufacturers in a better position than himself as regards the matter of perfecting and developing a given design. For the same

reasons he was unprepared to put forward any information as to the petrol consumption of his engine, but he pointed out that his two-stroke would be less expensive to make than the present-day four-stroke, while his four-stroke would also be less expensive to make than a present-day four-stroke of the same c.c.

Between squalls of rain the demonstration two-stroke machine was ridden by one and then another of those present. Conflicting opinions reached our hearing: many not particularly favourable, though allowance was made for the fact that the engine was a "botched up affair"—as its inventor constantly reminded us—produced under great difficulties. For slow running it certainly compared very favourably with a well-known make of two-stroke which was present, but we prefer to withhold our opinion as to its behaviour on the road. The machine has now been handed over to our staff to undergo a thorough road test extending over two or three weeks, at the end of which time we shall be better able to discuss its capabilities.

## Cancellation of the Petrol Licences.

THE Automobile Association and Motor Union recently protested against the cancellation of petrol licences issued for periods prior to April and May, 1917, and reminded the Petrol Controller that such licences carried an undertaking that they would be valid until all the monthly allowances were drawn.

In reply to the Petrol Controller's statement that the cancellation notice could not be withdrawn or modified owing to the critical petrol situation, the Automobile Association suggested that the notice be strictly confined to those petrol licences held by motorists who relinquished their 1917 Inland Revenue vehicle licences on June 30th.

The following correspondence has ensued:

August 11th, 1917.

The Secretary, The Automobile Association  
and Motor Union, Whitcomb Street, W.C.

Sir,—I am directed by the Petrol Controller to acknowledge the receipt of your letter of August 8th, and to express his regret that, in view of the urgent necessity for limiting the consumption of petrol available for civil needs to the essential trade and industry of the country, he cannot see his way to adopt your suggestion that the recent notice, cancelling out-of-date full duty petrol licences, should be confined to those held by motorists who relinquished their car and motor cycle licences on June 30th last.

(Signed) H. W. COLE.

August 16th, 1917.

H. W. Cole, Esq., Petrol Control Department,  
19, Berkeley Street, W.1.

Sir,—I have to acknowledge receipt of yours of the 11th inst. (reference No. 142,549), and regret that the Petrol Controller is unable to adopt our suggestion that cancellation of out-of-date full duty licences be confined to those held by motorists who relinquished their car and motor cycle licences on June 30th last.

In connection with your notice of cancellation, the Automobile Association is receiving a number of letters from holders of first and second issue petrol licences, who have used their allowances sparingly and solely for business purposes. They have depended upon being able to draw their allowances as and when required, and are now seriously handicapped by the notice of cancellation.

May I, therefore, suggest that the Association be permitted to bring before your Department such cases, in

order that they may be considered on their merits, with a view to the issue of fresh licences?

If you will kindly consent to this being done, I would assure you that no cases will be passed to you unless the Association is fully satisfied that petrol is really essential for business purposes.

STENSON COOKE, Major, Secretary.

August 18th, 1917.

Maj. Stenson Cooke, Secretary, Automobile Association.

Sir,—I have to acknowledge the receipt of your letter of August 16th, in which you call the Petrol Controller's attention to the position of holders of first and second issue full duty motor spirit licences who have used their allowances sparingly and solely for business purposes, and who are now unable to obtain supplies for such purposes owing to the cancellation of all out-of-date licences.

I am to say that the Controller is willing to accept your suggestion that the Automobile Association should be permitted to submit any such cases to him for consideration on their merits, with a view to the issue of fresh licences. No undertaking can be given that new licences will be issued in every case, and only those should be forwarded where there is satisfactory evidence that the petrol is really essential for business purposes.

(Signed) H. W. COLE.

The Secretary, H.M. Treasury, Whitehall, S.W.

Sir,—On behalf of a large number of motorists who are members of this Association, I am directed to place the following facts before you:

Owing to the increasing scarcity of petrol, a clause was inserted in the Finance Act, 1917-18 enabling motorists to obtain a refund of half their motor vehicle taxes paid for this year, on June 30th, upon surrender of their vehicle licences.

Advantage was taken of this concession by many unable to obtain renewals of their petrol licences, but others, who had small supplies in view through unexpired licences, decided not to surrender their licences in the belief that the promise or "undertaking" conveyed on their petrol licences of the first and second issues, that such licences would be valid until they were exhausted, would hold good.

On July 25th a notice was issued by the Petrol Controller cancelling unexpired petrol licences of the first and second issues.

I submit that motorists who have paid Inland Revenue licence fees for this year, and are now without petrol licences, should be entitled to claim a refund of such fees in respect of the period during which they will be unable to use their vehicles. I am, therefore, to express the hope that this very reasonable concession may be granted.

STENSON COOKE, Major, Secretary.

# Current Chat

## TIMES TO LIGHT LAMPS.

Aug. 30th	...	...	8.22 p.m.
Sept. 1st	...	...	8.16 "
" 3rd	...	...	8.11 "

## Quantity Production?

We understand that the price of a pair of handle-bars for a well-known American machine is to-day £4 10s. Is this the result of quantity production?

## High Second-hand Prices in France.

Our French correspondence this week reveals the abnormal prices prevailing for second-hand machines over the Channel. The following instances are given of actual sales: A 1912 Zenith (repainted) 1,800 frs. (£72), a seven months' old Rudge 2,300 frs. (£92), and a T.T. Rudge about two years old 2,400 frs. (£96). One writer mentions that the price asked for a new B.S.A. at Le Havre is 2,780 frs. (£110). If the War Office could dispose of the D.R. scrap heap at prices on this scale the question of war finance would be beyond doubt.

## Some Average Speeds.

A Yorkshire rider asserts that a 30 m.p.h. average is quite easy to maintain on a long trip, and that he has maintained 31 m.p.h. on runs exceeding 200 miles in length. An average speed of 36 m.p.h. or so he considers to be practicable only on two hour runs or thereabouts. We do not think anybody will deny either that 35 m.p.h. is practicable for two hours, or that 30 m.p.h. can be maintained all day. The real point is that either performance is such a weariness to the flesh that very few people would care to put it up.

## The Sale of Second-hand Machines.

A great deal of dissatisfaction would be avoided and trouble saved both to purchaser and vendor of second-hand motor cycles if care were taken to verify the date of manufacture by the engine and frame numbers. Makers are always glad to supply this information. It frequently happens that a vendor, with the best of intentions in the world, sells a machine as, say, a 1916 model. The purchaser does not know differently, buys it as a 1916 model, when he suddenly has a brain wave, discovers the engine number, and communicates with the maker. The maker gives the date as, say, 1915, and there is at once trouble, heart-burning, and ill-feeling. It would not be at all a bad plan if those who have motor cycles for sale were to quote the engine and frame numbers in their advertisements, so that prospective buyers could verify the date of construction.

## The Petrol Position in America.

There seems to be no doubt that the American petrol producers are not having the way made too easy for them, and the result will be an undoubted rise in the price of petrol over there. In the meantime, American motorists are advised not to stop riding, but to avoid waste by rendering their carburetters economical.

## Hercules Reclaim Service.

Mr. F. W. Farr, the patentee of the Hercules Reclaim Service, is now in France, with the object of starting a factory there for undertaking tyre repairs under the French patents. It will be remembered that the special feature of this system is that, although the two covers are sewn together, there are no stitches on the inner surface to ruin the tube.

## Where the Petrol goes.

One of our latest model bomb-carrying planes consumes as much petrol in one hour as would carry a solo mount, say, of the Douglas order, a distance of approximately 2,000 miles—a season's riding for the average man! Those who live in districts where aero engines are made, and hear these mammoths droning away for hours on end under test, realise where some of the petrol goes.

## Overloaded Sidcars.

On the occasion of a recent tramway strike in Seattle, when the populace was stranded for means of locomotion, grossly overloaded motor cycles and sidcars came to the rescue. We are informed that none of these seemed any the worse for the ordeal through which it had to go, but no practical rider would countenance such gross misuse as the overloading of his own machine, which is too often practised by the novice.

## SPECIAL FEATURES.

ROAD TEST OF AN OVERSEAS MODEL.  
A POWER UNIT WITHOUT MAGNETO.  
FRAME DESIGN AND THE FLAT TWIN.  
DEMONSTRATION OF A NOVEL  
TWO-STROKE.

## A Malicious Act.

For putting nails and screws on a road over which there is a large amount of motor traffic, two youths, one 18 and the other 14, were fined 45s. each at Grantham last Saturday.

## COAL GAS INSTEAD OF PETROL.

The illustration shows a 2½ h.p. Douglas motor bicycle and sidcar equipped with a gas-bag supplied by Messrs. Andrew Barton Bros., Beeston, Notts. The gas-holder contains twenty-one cubic feet, which is equivalent to rather less than one-fifth of a gallon of petrol; the bag is held in tension from each end, and so arranged that it automatically closes as the gas is used up. It weighs rather under 6 lb., and, when fully inflated, the contents are less than a halfpenny in value. As the machine will travel ten miles at a cost of under a halfpenny the expense of running does not seem to be excessive, though the range of action is naturally distinctly limited. The machine may be seen at Barton Bros.' Nottingham depot.

### The National War Funds.

At the week-end the principal relief funds stood as follow:

The National Relief Fund (distributed £3,641,622) ..	£6,226,436	0	0
The British Red Cross Fund ..	7,233,140	4	8
Tobacco Fund .. .. .	135,875	0	0

### Taking Safety for Granted.

The danger of taking it for granted that the road is open was shown when, last week, a motor cyclist, riding a four-cylinder F.N. and sidecar, crashed into a Ford van, standing at the roadside. This accident occurred on a straight length of the Portsmouth Road between Thames Ditton and Esher. The motor cyclist was looking down at his engine, and, although the road was otherwise clear, ran straight into the van. He was thrown over the handle-bars on to the tailboard of the Ford, but received only slight injuries. The front forks of his machine, however, were driven back on to the steering head, and the front down tube of the frame was split round the whole of its circumference just below the tank.

### The New Order of Knighthood.

Last Saturday the first list of appointments by the King in the new Order of Knighthood, the Order of the British Empire, and a new Order of Companions of Honour was issued. Several prominent gentlemen in the motor world figure in the list: The Hon. Sir Arthur Stanley, M.P., Chairman R.A.C., Chairman British Red Cross Society and the Order of St. John of Jerusalem: Knight Grand Cross. Sir Herbert Austin, managing director of the Austin Motor Co., Ltd., for valuable services in the production of munitions; Sir Dugald Clerk, the well-known gas and internal combustion engine expert, who is a member of the Panel of Board of Invention

and Research, Admiralty, the Ministry of Munitions Inventions Department, and of the Trench Warfare Advisory Panel; and Sir Alfred E. Herbert, Deputy Director-General in charge of the Machine Tool Division, and Chairman of the Machine Tool Committee at the Ministry of Munitions, who before the war was a manufacturer of lathes and machine tools used in automobile construction: Knights-Commanders of the Order. P. L. D. Perry (Ford Cars), Director of Agricultural Machinery Department, Ministry of Munitions; H. Tempest Vane (formerly Napier Motors), service on War Office and Munitions Work: Commanders. G. H. Bailie, Chairman R.A.C. Technical Committee, Chief Technical Advisor, Labour Supply Department, Ministry of Munitions: Member.

### Assault and Battery.

An interesting case came before our notice the other day. A motor cyclist was riding through a London suburb, when some distance in front of him a pedal cyclist fell over. The motor cyclist slowed down, glanced round, and seeing the cyclist pick himself up, rode on. He had not travelled more than about 300 yards before a man walked across the road and signalled him to stop. The motor cyclist continued his journey, blowing his horn, but as he passed the gestulating individual, the latter struck at his head with a thick stick and inflicted a severe wound on the motor cyclist's right temple. The blow was so violent that it cut through a thick cap the motor cyclist was wearing and smashed the stick. The motor cyclist pulled up with great difficulty, as he was nearly stunned, and then questioned the person who had assaulted him, who gave the

amazing explanation that he had acted in this manner because the motor cyclist had knocked over the cyclist and was running away to escape the consequences. Fortunately, the motor cyclist had sufficient presence of mind to give the person who had assaulted him into the custody of a policeman. In due course the case came off and there was no defence, and it was suggested by the Bench that the individual should compensate the motor cyclist. The result was that the matter was settled out of court on the individual paying £10 as compensation to the motor cyclist, the defendant also agreeing to pay all fees and expenses.

### Average Prices.

We give below the prices of second-hand machines offered for sale in the last issue of *The Motor Cycle*, and in the adjoining column the average prices based upon the latest figures available. Thus the general trend of the market is visible at a glance, though in the first column many blanks inevitably occur. This is due to an insufficient number of one model on which to base an average, or to the lack of other essential particulars.

### AN ANTIQUATED DEVICE.

An ancient drawbridge between Petersbrooke and Earlswood. The projecting beams are weighted with stones enclosed in boxes, the structure being so balanced that an old man can, with the aid of a winch, draw the bridge upwards to allow canal traffic to pass. A Sunbeam sidecar is seen crossing the bridge.

## MOTOR CYCLISTS IN FRANCE.

An Appreciation of the Wonderful Work of Despatch Riders and Orderlies.

By J. FAIRFAX-BLAKEBOROUGH.

IF I were asked what has struck me most of all the strange and exciting, sordid and sad, horrible and horrifying scenes I have seen on the two most active Fronts in France last winter; if I were asked who had gone bravely on with least recognition or hope of glory or limelight . . . I should unhesitatingly answer these two questions with the words—the motor cyclist. Be he despatch rider, orderly, or what-not, the motor cyclist on the Somme and on the Arras side has exhibited a fortitude, a courage, daring and marvellous quickness of action and decision a hundred times a day. The infantry have been simply marvellous—no words would over-estimate their wonderful work or describe all they have gone through. But they have experienced no worse conditions than the motor cyclists, and when they have “gone over the top,” they have done so in concert with the vitalising effect of excitement, a leader—someone to command. There is great sympathy in a crowd, and there is much confidence inspired by a good leader. The motor cyclist stands, or rather works, alone. He is given some point on the map, and, in darkness and storm, it may be, he has to find some person among a thousand. He has no one to accompany him, no one to help him to decide at a crucial moment when courage, rapidity of action, steadiness of nerve, and nice judgment of both space and pace may stand between himself and a buckled wheel or broken leg.

### Wriggling through Traffic.

I have watched by night and day and early morning these motor cyclists—covered with mud and snow and water—worming their way through every form of traffic, carefully, quickly, and successfully, with admiration and amazement, and I have more than once said to brother cavalry officers with me, “If those men could only ride a horse as well as they ride a motor cycle what wonderful jockeys they would make.” One has so often seen races lost simply because a jockey has not had the pluck or the quickness of action to force his way through an opening between other horses. So has one seen races won by jockeys seizing an opportunity of breaking through a momentary gap and coming in and winning. There is all the difference in the world between the average gentleman-amateur rider and the professional jockey in this respect. The one is lost in a crowd: the professional can judge pace and make the most of opportunities to “get on.” That is exactly what the motor cyclist out here does. He is an opportunist with nerves of iron, a clear head and eye, and a knowledge of space and pace—he sees a gap and can judge whether he can be through it before it closes.

Sometimes I have seen cyclist orderlies squeeze through with a floundering motor tractor on one side of the road and a team of nervous, shying mules on the other. I have simply held my breath, and expected to see a mangled mass of crushed flesh and blood the result, but before I have recovered he has been on his way with his message to “corps” or “brigade,” to “Q.” or some general. I have seen them riding between two columns of traffic—both miles long, travelling in opposite directions, on narrow roads, a bog everywhere and punctuated with shell holes. I have watched them wriggle through, pass restive or exhausted and fallen horses, and great heaving, rolling motor lorries, and wondered. I have watched them when hail was driving in their faces and they could hardly look up, when they have had to ride in a gutter almost knee deep in mud for two or three hundred yards, and I have thought, “My God! You are amongst the heroes of the war. . . . You are brave men indeed!” . . . For, mark you, I have painted my word-picture badly if I have not conveyed to the reader the dangers, the difficulties, and hardships of the road both day and night prior to the fine weather which came with May. I have not dwelt upon the indescribable conditions of the roads, in which when a horse falls he sometimes sinks and is lost, and on the top of some parts of which sleepers, put down to try and make a surface, float instead. I have not touched upon the shelling of roads at night, the blockades for hours and hours, and all the incidental dangers and difficulties, but they all have to be overcome by these courageous “pilgrims of the night.”

### The Search for Objectives.

When we have been moving almost daily I have known them come from H.Q. (Headquarters) in the most violent storms, at two, three, and four in the morning, sometimes with only a vague map reference to go by, “You’ll find them somewhere about there.” “Somewhere about there” might mean we were on a bog with half-a-dozen other units (none of them quite clear who their neighbours are), camped half a mile from the high road, with a knee deep in mud approach from that road. Imagine this in storm and darkness, the search for the particular commanding officer or adjutant required, the vague directions and definite misdirections, the return to H.Q. in more storm (and every day of February, March, and April seems to have brought its storm), only to find fresh orders—possibly cancelling the first—to be taken to the same place. And there are those at home who have imagined, and *do* imagine, that riding a motor

**Motor Cyclists in France.—**

cycle in France is what is known amongst soldiers as "a cushy job"!

**They Enjoy their Jobs!**

I once asked one of these despatch riders how many of them were attached to his particular H.Q., and he told me two, so that when possible they alternated with night and day duty. Of course, some H.Q.'s have a perfect army of motor cyclist orderlies who keep generals and staff and subordinate commanders in constant touch, especially on the move, when, of course, no telephonic communication can be established. I have come across some of these brave lads who are public school boys, and who love the excitement of their job, but this fact (I mean the fact that they get pleasure out of their job) makes them none the less heroes. They have done excellent work under conditions which could not well have been worse for man and machine, and when the story of the war comes to be written they will deserve a chapter printed in heavy type and red ink, for they have come

in for little honour and glory during these three years of hardship—mud, filth, and squalor, to say nothing of danger. What Henri Barbusse says in "La Feu," written last year, applies most eloquently to the motor cyclist heroes of whom I write, especially when he speaks of the endurance; of the mud that

"glues the *poilu* to the earth"; of the cold that freezes him into a statue; of the vermin that rob him of sleep when he does find opportunity to lay him down; and of rain and snow and mud soaked through his clothes—these three the very hell of war—which chill him to the marrow. Yet our English boys—and they are often little more than boys—with cold-skin - peeled faces and frost-bitten ears, have still kept on smiling on their mud-coated motor cycles.

Besides merely being clever riders, D.R.'s have necessarily to be clever mechanics, and able to undertake other than those which are designated "roadside" repairs. In the hotel yard, which these incorrigible humorists have designated "Hotel Clutch and Gear Box," despatch riders are seen adjusting the clutch springs of a W.D. Triumph.

Yes! it gives me real pleasure to pay this tribute of honest admiration for them, as I trust it will be paid in the history of the war.

Fortunately, now the weather has changed, and we are living in scorching heat and clouds of dust. The motor cyclist, in consequence, now leads a life of comparative pleasure to that of a few months ago.

## Keep up the Revs. A Few Driving Hints.

IT is very often that the ultra careful rider, who is desirous of saving his machine and economising in every way possible, drives atrociously badly, and, if he knew it, goes entirely the wrong way from achieving the results he so much desires.

The man who is frightened of opening his throttle does not save petrol, and generally he abuses his engine. If he took for his motto the phrase, "Keep up the revs.," he would do much better in every way. Particularly does this apply in the case of a single-cylinder machine with sidecar attached.

Most careful riders hate to hear their engines turning over at anything approaching high speed. They approach a hill in a leisurely manner, allow the engine to konk along at slow speed, postponing the change down till the last moment, and even in low gear they keep the speed of the engine down so that the force of each explosion can be felt.

This is entirely the wrong way of going about it, and while it does an engine no harm whatever to turn over at high speed, this overloading at low speed is apt to do very considerable harm. Let us imagine what it means. Every stroke of the engine delivers—a jar throughout its bearings and throughout the transmission system, whereas, if the speed of the engine be kept up, the torque is more or less even. Moreover, when an engine is running slowly on heavy load the hot, slow explosion causes pitting of the valves, high oil and petrol consumption.

"It is the hammer-hammer-hammer" that does the harm. In hill-climbing, approach the hill at a goodly speed, and change early, allowing the engine to keep up a lively purr throughout the climb. In changing down do not close the throttle, but allow the engine to pick up during the fraction of a second that the gear is in free.

B.

# FRAME DESIGN AND THE FLAT TWIN.

## Dealing with a Common Weakness in Present-day Design.

ONE of the most frequently heard criticisms of all those that are levelled against the flat twin is the complaint that it is a most ungrateful unit to deal with when designing a frame for its reception, and certainly the more one has to do with it the more one realises that this, indeed, is the most powerful obstacle in its progress and development.

It often happens that the infusion of "new blood" into a movement results in very rapid and noticeable improvements, but despite the fact that the firms who have taken up the production of flat twins are mostly "newcomers"—that is to say, they did not graduate through the push cycle and early motor cycle periods—they have shown a disappointing lack of feeling for correctness of frame design.

Naturally, the engine being the all engrossing interest of the designer, it is not difficult to understand that the laying aside of an attractive unit until the problems of housing it had been thoroughly overcome would be too great a sacrifice, and in consequence frames have been manufactured which can lay no claim to scientific principles, and may be regarded merely as makeshifts which hold together, more or less successfully, by virtue of the weight of metal in the vital parts.

### A Universal Weakness.

The weakest element in the motor cycle frame (irrespective of type) is the front down tube, and to make any departure from the straight line here is fatal, therefore to dodge that obtrusive front cylinder a duplex front construction appears inevitable. (On the score of increased lateral stability I think this a desirable feature in *any* frame.)

It is tolerably easy to sketch out an elevation of a frame to contain a moderate-sized flat twin and countershaft gear box, embodying the above principle and maintaining a pleasing appearance, but having established this general outline let anyone sufficiently interested now attempt to draw a plan view of the engine and transmission showing the frame tubes in a section taken just below the tank.

Allowing the same freedom in the disposition of such engine parts as the exhaust and inlet systems, transmission and fittings, as would be allowed to the designer of the complete machine, it will nevertheless be observed that there are many difficulties in the way of completing a compact frame preserving the straight tube ideal.

That other people have been over the ground before and have wrestled with its difficulties I may illustrate by recalling the experience of a certain firm which obtained a flat twin engine of considerable size and power. The "heads" insisted upon the use of duplex, straight tube principles, and a very sound but abnormally heavy and clumsy frame was evolved.

The satisfaction of the designer was rudely dashed when he discovered that the united efforts of two mechanics for several hours were necessary before the engine could be induced to fall into position!

### Advantages of the Duplex Frame.

It is supposed in the suggested sketch elevation that the whole frame is duplex with the possible exception of the sloping top tube, and that the horizontal members supporting the engine and gear box are either light channels or stout plates to the extremities of which the various frame tubes are secured by means of long bolts and distance pieces.

Whilst not being absolutely complete in detail the design indicates the pleasing appearance given by the application of straight tubes, and also that no startling departures from "standard" outlines should be necessitated; it also embodies a long steering head, a desirable feature too often ignored in the effort to preserve the horizontal top

tube. The most objectionable feature is that the countershaft centre falls so far outside the engine and hub centre line (here again we are up against another of those attendant difficulties seemingly inseparable from the type), but granting sufficient stiffness in the lower compression members of the frame the effect of the stresses set up by the drive would be negligible.

There has been much beating of the wind by learned gentlemen who are capable of "proving" that the flat twin is streets ahead of its competitors in the matter of mechanical perfection, but perfection lies in all-round perfection. An engine, however excellent, is conceivably a cause of trouble if its design be such as to render impossible a good type of frame.

In short, an insistent demand must be raised to the manufacturers that they pay more attention to the elementary principles of design as applied to flat twin construction, for as long as bent tubes (especially of D sections) are employed so long will the idea live that the flat twin cannot be built into a decent frame.

WHARFEDALE.

The author's design, in which he claims to have eliminated certain common weaknesses in flat twin frame design.

## MILITARY NOTES.

## Types of D.R.'s. Revision of Medical Categories.

## A YOUNG D.R.

LETTERS and photographs continue to reach us respecting young D.R.'s. Mr. F. J. Raymond, speaking of his son, says:

"With reference to the letters appearing in your useful paper regarding young despatch riders, I should like to mention that my son, Cpl. F. Raymond, joined in August, 1914, at the age of 15 years and 9 months, and sailed for India in that year as a D.R., and after serving there for some time volunteered for Mesopotamia, and is acting as a despatch rider attached to the H.Q. Section Army Signallers. As we send him

every week, the letters should be interesting reading for him."

## TWO CLASSES ONLY FOR ARMY.

A FURTHER revision of the medical categories for recruits may be expected shortly, says *The Times*. The details have not yet been worked out, but it is understood that men fit for military service will be classified under two heads only—those fit for service in the field, and those who, without any organic disease, are unfit for active campaigning. These may be classified as Classes 1 and 2 of only one category, probably A. The second category may consist of men who, unfit for any form of military service, could still do war work in connection with national service at home.

## TYPES OF D.R.'s.

A DESPATCH rider on active service speaks of a "type" of D.R. which the contributor of "D.R.'s and Their Work" did not mention: "As an interested reader of your paper, and also as a D.R. 'out here,' I should be pleased if you will allow me to make a few remarks on your articles, 'Who is the youngest D.R.?' appearing in your issues of July 19th and 26th. Probably nobody has taken the trouble to reply to Mr. Roughley's statement (or query), but the morning I received your paper I questioned one youthful-looking chap on the subject, who said he enlisted with a friend when their ages were 17 years 2 months and 17 years 4 months respectively. This D.R. has been on active service nine months with a Divisional Signal Company, and was prevented coming 'out' before on account of his youth. I and nine others have served twenty-eight and a half months with the same Signal Company, and came 'out' on November 7th, 1915—twenty-one months, and still going strong, even though 'fed up.' Your article 'D.R.'s

and Their Work' has prompted me to write, as your contributor does not mention in his 'Types of D.R.'s' (one who is detested by most D.R.'s) the 'Swank.'"

## ONE OF THE FIRST WITH THE TANKS.

FRED BARNES, a Coventry Rudge enthusiast, writes from St. John's Hospital, Canterbury: "I noticed a photograph of Gnr. Jakins, one of my old

Fred Barnes, well-known in the Midlands as a Rudge exponent. He was wounded by shrapnel at Messines.

chums of the Tanks. I am enclosing a photograph of myself and Triumph, taken while in France as a D.R. for the Tanks. Unfortunately, I was wounded at Messines on June 7th, 1917, with shrapnel bullet in my left foot, but I am now on the high way to recovery. Previous to being in the Tanks I was with the Motor Machine Gun Corps training at Bisley, which was one of the first to be formed into Tanks."

C. G. Probert, who is nineteen years old, and has seen eleven months' service Overseas.

## MOTOR MECHANIC AT 17½ YEARS.

"H A V I N G read the interesting letter from your Rochdale reader, who wished to know who is the youngest motor cyclist despatch rider to go on foreign service, I would like to raise the question: 'Who is the youngest motor mechanic to go on active service?' as my son, H. T. J. Jacobs, at the age of 16½ years joined the United Art Forces as a despatch rider. After serving for six months he joined the Motor Machine Gun Corps, attached A.C.S. (M.T.), as a mechanic, and then transferred to the 1st Armoured Motor Battery, and at the age of 17½ years went on active service as a mechanic to British East Africa, and has been serving abroad for the last eighteen months.—S. JACOBS."

Cpl. H. T. J. Jacobs.

## ANOTHER YOUNG D.R.

E. C. DAVIS, writing from "somewhere in France," says: "I have noticed in 'Military Notes' in the 'Blue 'Un' for two consecutive weeks a paragraph on who is the youngest D.R. I enclose a photograph of a friend of mine in our company, who is not younger but equals the claim of young Roughley. My friend, C. G. Probert, is called the 'Baby of the Company.' I trust you will give this the same publicity as in the case of young Roughley, and wish *The Motor Cycle* every success. I can assure you it is eagerly sought for by all the boys."

# THE Critic

## Fireside Chats on Motor Cycle Problems

### BRAKES.

THE D.R. had been laying down the law with regard to front wheel brakes. "As it stands to-day," he said, "it is merely an inflection, existing to comply with the law. It is of no use; it is a possible source of danger, as witness the case of a rider in Scotland who was killed a year or so ago by the brake block twisting round and jamming the spokes. The law demands two brakes, so let us have two of the sensible variety contained in the rear wheel."

"I disagree with you entirely," stated the Manufacturer.

"So do I," chipped in the Journalist.

The D.R. looked surprised. "What in the name of fortune is the good of a front wheel brake?" he demanded. "You seldom use it. If you do you are likely to come a cropper. Its only use is that it complies with the law, and the in-operative variety is probably the safest."

"You always ride solo," the Journalist pointed out. "In which case a front wheel brake is certainly not of much use; but in the case of a sidecar machine, it is not only desirable, but necessary. If once your rear wheel starts to skid, you are done."

"What's the matter with the Indian as a sidecar machine?" snorted the Discharged Soldier.

"Only one thing," the Journalist enlightened him. "It is short of a front wheel brake."

#### Why Two Brakes?

"I might ask you," put in the Manufacturer—"What's the use of having two powerful brakes on the rear wheel, when either one of them is sufficient to skid the wheel? Now listen. A leading Coventry firm recently experimented with the two rear wheel brakes—internal expanding and external contracting. When this firm's design was carried into practice, not only was it found wanting in other respects, but the rear wheel actually weighed more than the three-speed hub gear originally fitted!"

"Clumsy design," growled the D.R. "Two rear wheel brakes need weigh only a few ounces more than one."

"But why have two of them, when one will do all that can be done in the way of stopping the wheel?" queried the Journalist. "The idea is absurd on the face of things. You must admit that the second brake, demanded by law, can be put to some useful purpose. The maximum braking effect is when the wheel is nearly, but not quite, skidding. Immediately it begins to skid the power is lost. Now by braking both wheels—the back wheel to the maximum point—the retarding effect is obviously much greater than if only one wheel be braked."

B16

"As a matter of fact," put in the Manufacturer, "the front wheel is, theoretically, the correct place for a brake, because, when the impetus of the machine is being rapidly checked, all the weight is thrown on the front wheel, and consequently, in the case of a sidecar outfit, it is probably the better wheel of the two to depend upon."

#### An Abomination.

The Novice observed that the D.R. was getting rather more than he asked for, at which the latter observed, "Don't be a blithering ass. Lend me a match." After he had lit his pipe, he proceeded: "I admit that there may be something in what you say for sidecar machines. I have never ridden them in competition over mountainous routes, but I know that if the rear wheel begins to skid on a bad descent it is the very dickens. In such a case a good front wheel brake might save disaster, but all that does not alter the fact that the front wheel brake as it stands to-day is an abomination of desolation."

"If you fit good leather blocks instead of fibre blocks it grips a hundred times better," mildly put in the Novice.

"I don't care a straw," stormed the D.R., "the whole principle of a rim brake—operating on a plated rim above all things!—is a relic of an undesirable push-cycle practice."

The Manufacturer sat up and snorted loudly. The Novice, feeling nervous, brushed his waistcoat. The Journalist puffed hard at a cigar given him that day by the patentee of a novel two-stroke.

"We have others," presently observed the last named gentleman. "What about the Lea-Francis and the Allon?"

"The exception proves the rule," admitted the incapacitated soldier. "And anyway two mushrooms don't make a boiling. For those two I can mention practically every other leading make in the kingdom who fit the old rim variety."

A long silence followed. "It comes to this," the Journalist finally summed up, "that the present day front wheel rim brake is a farce. We want something better. If we are to have two brakes, we may, at least, have two which will work. On that we are all agreed. Now what about rear wheel brakes?"

"Hullo! he's after copy," observed the Novice rudely.

"I don't wonder," laughed the D.R. "If many more of our debates are going to be taken against us, we shall have to appeal to the trenches for reserve subjects. Anyway, what about rear wheel brakes?"

"I do not think the subject permits of much argument," said the Manufacturer. "I think it is finally decided that the internal expanding metal-to-metal variety is to supersede all others."

"Not a bit of it!" stated the D.R., peremptorily, prepared, after his recent dressing down, to contradict everything the Manufacturer said, even at the cost of contradicting himself. "It may be all right for your touring limousine family tramcar outfit, but the solo rider doesn't want it. Give me the simple tension rod and leather shoe on the brake rim. It scores on the points of cheapness, lightness, accessibility, simplicity, and visibility."

"And if you get a little grease on your rim it is still visible and simple, but it is no longer a brake," sniffed the Journalist.

#### Personal Opinions.

"And if you get a chunk of fluff in your jet it is still a jet, though it no longer functions as such," snorted the D.R. "Simplicity, cheapness, and lightness score. I have no quarrel with the old brake shoe variety. For the T.T. solo mount it cannot be beaten."

"O my stars!" gasped the Manufacturer. "This selfish blighter is obsessed with solo mounts! For goodness sake widen your ideas, man!"

The Journalist, feeling his responsibility as host, took command, while the D.R. stared vindictively at the Manufacturer. "I have recently been riding as solo mounts a Velocette and an A.J.S.," the Journalist explained. "On both these machines the metal-to-metal brakes were superb. As for the weight question, I never noticed it."

"Not likely to," sneered the D.R., "considering you never tried either machine minus its heavy rear wheel mechanism. In the case of a lightweight particularly, there should be as little weight as possible in the rear wheel."

The Manufacturer regarded him narrowly. "Which weighs the more," he queried, "the expanding brake, which uses the sprocket as a drum, or your precious shoe brake, with its special belt drum on which to operate?"

But the D.R. was losing interest in things. It was one of his off nights. He observed, by way of a soliloquy, that he thought the Manufacturer drank too much, while the shape of his nose was disgusting. As for the Novice, he was getting horribly fat—a most loathsome exhibition. "Give me the Indian," he added, "minus a front wheel brake, and with its internal expanding—No what in thunder do I wait?"

But no one attempted to answer.

# LETTERS to the EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

## PETROIL LUBRICATION.

Sir,—We feel it necessary to contest a statement in an article appearing in last week's issue of *The Motor Cycle*. It is surely erroneous to state that the petrol system "has been acknowledged to be the most satisfactory method of lubrication for a two-stroke." We think that if you had written "unsatisfactory" you would be much nearer the mark. We should like to know who has "acknowledged" this system to be superior. We think it to be far more generally acknowledged that the petrol system has two advantages only, viz., it is automatic (in a crude fashion) and foolproof, subject, of course, to the proviso that if the rider is fool enough he might forget to put the oil in at all, which is not unknown. The disadvantages of this system are almost too well known to need recapitulation, but, having stated its advantages, it is only fair to state the other side. The great failing with the petrol system is its inefficiency and its incapability of adequately lubricating the main bushes. The abnormal wear of main bushes lubricated on this system as compared with the Levis system is very noticeable, and we contend that our bushes will last three times as long as those lubricated with petrol. Its other general disadvantages are that it is frightfully messy, it tends to gum up the piston rings, and, unless an excess of oil be given for all other times, it does not adequately lubricate the engine when ascending a stiff hill.

We think no more significant admission has been made than the statement made by Mr. Archie Cocks, of the Connaught and Clyno fame. Mr. Cocks, in the course of his short speech at the demonstration of the Tilston engine at Stonebridge on Wednesday, August 22nd, laid claim to being the first exponent of the petrol system of lubrication in this country, and confessed that, while the petrol system was quite efficient for pottering about, he had found it "quite unsuitable" for long journeys or a hard day's run at 20 m.p.h. average.

We think that this statement made in public, coming from Mr. Cocks, who has so long been connected with and who boosted the petrol system, is sufficient "acknowledgment" of its being unsatisfactory. BUTTERFIELDS, LTD.

## THE CRITICS.

Sir,—If I had to serve with "Howitzer R.G.A.," whose letter appeared in your issue of August 16th, I should keep an eye on him, lest he shot me in the back. He seems anxious to treat the British motor cycle manufacturer in that way. He admits that ten years ago the British manufacturer had an absolute lead; he had, but he did not start with it, and, if the plain truth be told, the British manufacturer held that lead right up to the beginning of the war. Proofs—he held the home market and could not turn out enough machines for it; he had captured, without trying very hard for it, the bulk of the Colonial and foreign trade, and was only kept out of America by a tariff wall, though there was no tariff wall to keep Americans out of Great Britain. Did the American wipe the floor with the British manufacturer in the T.T. races? Does he do it in the Colonies? All of which is not bad for "half educated, pig-headed, purblind tinkers."

His cheap sneers at the pitiful two-stroke can be allowed to pass, but can he produce a two-stroke built in America (which is the home of this type of engine) which can surpass the performances of, say, the Levis? Do the American two-strokes, introduced as a "feeble and remote copy" of British machines, excel them in any particular relating to engine efficiency, cleanness, and general suitability for the purpose for which they are offered? I say they do not.

If "Howitzer" will acquaint himself with American designs he will find that there are copies of the Triumph two-stroke which as copies are neither feeble nor remote, but full-blooded and slavish as copies. The pile of wires, etc., etc., may be awful when of British origin, but the American sidcar combination is—more awful! (I nearly lapsed into military terms.)

The properly trained motor cycle engineer is all right, but there is not enough of him to go round—even in America. I question whether he is born yet. But the p.t. engineer is sometimes a trifle *difficile* in a motor cycle factory. Engineers did not originate the bicycle, and the best features of motor cycles have usually been introduced in spite of the trained engineers—who are, however, excellent fellows.

Is it not surprising that for years prior to the war the prices of the British motor cycles steadily went up, and the highest priced machines were always the hardest to get? Will "Howitzer" ponder that; also that the double purpose idea is not the manufacturers', but the users'.

I believe it is possible to discuss and compare British and American machines without desiguedly disparaging either, but, when comparing their performances, do not let us forget that a motor cycle can usually make a show of some kind if the engine is big enough for a car.

"Howitzer" is "fed up" with writing; I know—and I have reason to know—many riders, manufacturers, and others are fed up with reading stuff that has only one object, to decry British machines and laud up the Americans.

In conclusion, see what the British manufacturer will have to offer after the war.

EX-SERGEANT, M.M.G.

## COOLING THE ELECTRODE.

The air-cooled sparking plug with ventilating funnels referred to in G. Funck's letter.

Sir,—*Apròpos* the sparking plug design suggested by your correspondent, Mr. Geo. J. Hide, in your issue of August 16th, in which the hollow central electrode is cooled by means of an induced current of air, I think that the plug designed by myself, and patented by Mr. G. St. B. S. Watkins, would be of interest to your readers.

It will be seen from the accompanying illustration that this design is very similar to the one suggested by Mr. Hide. It was fully described in *The Autocar* of September 9th, 1916, and also in *The Light Car* at about the same time. The cooling draught which circulates through the electrode can be forced by means of a simple cowl or by connecting the electrode to the induction pipe, in which case it could act as an auxiliary air supply, feeding hot air to the engine. I have worked out a variety of designs, but the plug shown is probably most applicable to a motor cycle engine.

—GEORGES FUNCK.

## WHICH TYPE OF ENGINE?

Sir,—Considerable discussion is still taking place I notice as to the type of engine which will be most popular after the war, especially for the passenger type of machine. I quite agree with "Ixion" that the V twin is an abomination—for its weight, for instance, as well as for the reasons he states in the issue of *The Motor Cycle* for August 16th. He suggests the four-cylinder as its successor, but why is it that every writer on this subject deals with the present type of engine, and never suggests that great and extraordinary developments may take place, and an entirely new type of engine be produced?

By a new type, I mean one new to the public, for the files at the Patent Office reveal very numerous attempts to solve the problem, and by what I have recently seen I am convinced that the problem has been solved, and that we shall soon have a 10 h.p. engine weighing about 30 lb., with no cranks, connecting rods, or reciprocating pistons, giving two power strokes per revolution, with two sparking plugs—a natty little engine contained in a case about 9in. x 4in. Look out for something thrilling from America in this line, unless our British manufacturers buck up and get in first.

QUI VIVE.

## FLAT TWINS.

Sir,—In glancing through *The Motor Cycle* of August 2nd I notice that those "terrible twins" are on the carpet again, viz., "Ixion" and a critic—"Wharfedale," page 116.

These are strenuous times, and particularly so to the engineer who is trying to "carry on" with the aid of a "diluted squad," hence when "Wharfedale" refers me back to page 66 I accept his statement unquestioned and save time, but I enclose herewith particulars of an arrangement which may help to dispel some of the gloom surrounding the points (3 and 4) which he raises regarding "the unbalanced couple in existing flat-twin engines."

The Alder horizontally-opposed engine (patent 12,314, May, 1914), designed to eliminate the couple inherent to engines of the flat twin type. Theoretically the balance of this engine is perfect, but the design is reminiscent of an experimental Humber model. (See accompanying letter.)

In this engine the cubical capacity of the two small cylinders is exactly equivalent to that of the opposing large cylinder, and, of course, the cranks and pistons of the two small cylinders are equal in weight to those of the large cylinder. There is no increase in complications, for the two small cylinders having a common combustion head, only one exhaust valve and one inlet valve are necessary. I have designed a two-stroke marine engine on the same lines.

The advantages of this system of engine construction are: (1.) All moving parts are in perfect balance. (2.) The shock due to explosive force is completely abolished within the engine. (3.) Friction on crank case bearings is reduced to a minimum. The patent covering this engine is dated May, 1914. Certain events happening in August of that same year must have put "the tin hat" on many similar propositions.

STANLEY ALDER.

## INVERTED CONTROL LEVERS.

Sir,—I note in your issue of August 16th a letter from Capt. Lindsay re handle-bar levers.

I got so fed-up with the standard pattern clutch lever on my Norton that I put the control on to the inverted lever some six months ago with an ordinary Bowden lever which I had by me for the exhaust lift, which is comparatively little used.

This is a great improvement, and I shall certainly stick to it in future.

I must say I cannot follow Capt. Lindsay's argument about the anatomy of the hand and the various types of lever.

B20

Granted that the strength—and, I think, the sensitiveness—of the hand resides chiefly in the first two fingers, it seems to me that the greatest power and accuracy of control will be obtained by these fingers working at the greatest possible distance from the fulcrum of the lever, i.e., with the inverted type lever, and I certainly find this to be the case in practice.

However, I suppose it is like the question of which way a carburetter lever should open, all a matter of habit and taste, and it is not much good arguing about it. I believe there are even some queer people who actually prefer the American twist grip control to any other!

With regard to the general question of internal v. external Bowden wires, my fourteen years' riding experience leads me to consider them both equally reliable, though I have always had a preference for the internal form as being neater and less liable to damage in case of a spill.

I have never had any difficulty in renewing an inner wire, the method being: (1) grease the wire, (2) thread it through towards the handle-bar, (3) sweat on the nipple at the handle-bar end, and (4) adjust the length and sweat up the nipple at the far end.

W. WM. EVANS.

## DIVIDED SKIRT.

Sir,—Could any of your lady correspondents inform me where I could obtain the pattern for making a motor cycling divided skirt, as I desire to make it myself rather than purchase it ready made?

(Mrs.) A. M. BUNCE.

## POLICE INTERFERENCE.

Sir,—With reference to "H. Aldred's" complaint in your issue of August 9th that he was stopped and threatened by the police of St. Helens, may I ask him if any action has been taken by them? I have saved my petrol and am contemplating a tour in North Wales, and I am trying to find out the possibilities of any interference.

ALFRED E. SKINNER.

## FORK STEMS.

Sir,—I first began to read your journal in the days when you printed the "Let us s'pray" advertisements of the well-known French carburetter, and my passenger carrier was a trailer, so I think I must claim to be an "old" rider in one sense at least.

I have derived benefit from many of your readers' experiences, as described in *The Motor Cycle*, and that is my excuse for describing a mishap which occurred to me recently whilst going from Sheffield to Matlock, as I hope I may prevent some motor cyclist from having the same sort of spill.

My outfit is a 1913 Chater-Lea-Jap, which I got cheaply and have overhauled, and, with my wife in the sidecar, all had gone well until we got halfway through Chatsworth Park. Here I noticed the steering become "queer," the front wheel having a curious tendency to run us off the road. I dismounted, and found the wheels were not tracking properly, but could find no proper cause for this. When we got about a mile through the park, however, the trouble was explained very forcibly by the crank case ploughing up the road for a few yards, while the passenger and I nearly "unloaded." When I got free (my ankle having become jammed between the sidecar spring and the chassis), I found the fork stem had broken off at the crown, and, to cut a long story short, we had to leave the combination at a farm near by, where it remains up to the present awaiting new forks.

Now, Mr. Editor, my reason for inflicting this yarn on your readers is this. I wish to warn them, in case of a sudden defect in the steering of a machine, not to go on and trust to it "coming all right." My folly in doing this might easily have caused serious injury to myself and my passenger, but for the fact that I was going comparatively slowly at the time of the smash. Another point I wish to make is this. In spite of the numerous breakages of fork stems and steering columns (attended in most cases by serious results), very little improvement has been made in this most vital part of the motor cycle frame. Is there any reason why the steering column and fork stem should remain of such small diameter? This is almost the only member of the "frame" consisting of a single tube, and, to my mind, the fork stem should be at least 1½in. or even 2in. in diameter for a heavy machine.

I hope my letter may be the means of directing the attention of makers to this neglected part.

W. H. BERESFORD.

## THE OILING OF HORIZONTAL TWINS.

Sir,—I notice that most horizontal twin motor cycle engines are still oiled by the splash system. Surely motor manufacturers might find a better method of oiling than this, now that the horizontal twin engine has been on the market for several years. It would not require a great inventive genius to do this, as gas engine makers have several methods in use with stationary engines, and run their oil pipes to the surfaces that require lubricating. I believe that different oils are used for different parts of a gas engine—thick oil being used for the cylinder, and thin oil for the crankshaft and big end bearings, and I cannot see why this should not be done on a horizontal motor of a motor cycle. A pump might also be fitted to draw the surplus oil from the crank case and return it to the oil tank, or even to another tank, and this oil could be used again after being cleansed at home. I am sorry I cannot experiment on these ideas, but I am too busy at present acting as a running target for the genus Hun.

B.E.F.

## MUD PLUGGER.

## SPARKING PLUG DESIGN.

Sir,—I have read with great interest some recent discussions on the behaviour of plugs of various makes in various engines. I would like to state my experience of plugs in a certain high-speed  $2\frac{1}{2}$  h.p. flat twin during 1913-14. This engine, after much experiment and tuning (?), would run up to 4,650 r.p.m. under advantageous conditions on the road, and maintain that speed—traffic and roads allowing—for hours at a time; but only when I had found the plugs which would stand up to it. I think I tried every well-known make of plug, including two advertised as "racing plugs"—the less said about these the better—and they all had a fair trial. There were single, two, three, four, and "umteen" point plugs, and only two makes gave anything like satisfaction; and eventually I came back to the make, though not the pattern, supplied with the machine, being, as some of your readers will have guessed, of Germhuh manufacture! Of the plugs mentioned above, many were good enough for ordinary touring, but would not stand up to a long "blind," the points overheating, and in one case the insulator split when the engine was on full load. Having observed that—on the "Fritz" plugs, when cleaning in the ordinary way—the carbon started to collect first on the plug body adjacent to the point, I turned down an eighth of an inch of the screwed part of the body, so that the portion where the spark occurred was barely one millimetre thick, and thereafter the plugs ceased to sputter, though the engine was often swamped with oil. I suppose this thin rim, as it were, having the gases on both sides, kept hot enough to burn the oil off with the help of the spark. I give this tip for what it is worth to your readers.

B.E.F.

S. A. BUTTEAU.

## A PATRIOTIC OPTIMIST.

Sir,—I have been a reader of the "Blue 'Un" for the last seven years, and have never till now ventured to write. I have always followed the sport very keenly, and have ridden numerous makes. I have derived what motoring knowledge I possess from your valuable paper, coupled with a little practical work.

One thing I would like to mention most particularly is that I have been a keen follower of the different competitions, speed trials, etc., that were held in pre-war days. It has been most noticeable that American machines of the big twin class have consistently put up bigger speeds than British twins of the same power, except in a few cases.

In the  $3\frac{1}{2}$  h.p. class their machines cannot stand against ours, as witness the astonishing speeds of the Norton, A.B.C., Sunbeam, Scott, etc. Even now the American machines hold the records for all big track rides, and have put up the fastest speeds in the world.

Now I must admit that speed is not a vital factor, looking at the question from the average rider's standpoint. Consistent reliability and economy concern him more, and for this the British machine cannot be beaten. What I would like to point out is this, that I believe our machines are capable of taking all records from the Americans, both in speed and reliability. Such firms as the A.B.C., Triumph, Norton, Matchless, Rudge, etc., will no doubt turn their attention to the manufacture of big twins after the war (the end of which I do not think will be long), and I hope will be

able to beat all American records. I believe the manufacturers of the A.B.C. are already busy with a big H.O.2, which, to judge by what their  $3\frac{1}{2}$  h.p. model can do, must be exceptionally "hot stuff." Machines which consistently perform with success in speed and reliability trials are naturally brought to the notice of the motoring public, who are no doubt influenced in their choice of a machine by its performances in trials, etc.

In the opinion of some of your readers I may have spoken too strongly on this matter, but when I see the American machine praised and fêted on every hand, it exasperates me, knowing as I do that it is in no way superior to our machines.

The American motor cycle may be in the limelight now as regards speed, but it will have to look to its laurels when peace is proclaimed.

I may say I look forward every week to *The Motor Cycle*, and have only missed it a few times in seven years, even managing to get it regularly while in France. Trusting I have not taken up too much of your valuable space, and, as "Eldon" said recently, "I hope for a speedy return of the good old days on the open roads with something that can shift between one's knees."

BLERIOT.

Blackpool.

## A DOUBLE-ACTING FOUR-STROKE.

Sir,—I read with great interest in *The Motor Cycle* of August 2nd the article, "The Double-acting Four-stroke." This kind of engine has taken up a lot of my spare time, and I think my results are an improvement on those of Mr. Hinks, as indicated by his design. At least, I have overcome the fitting of the awkward piston rings he has in an outside piston by not having that kind of piston; I only need two sets of the ordinary rings. I have no inner cylinder, so do not generate that extra heat, and I think all the other faults mentioned arise from this. I have an extra piston heat, but I have an idea for internal cooling.

Perhaps Mr. Hinks would like to hear further. I am only a working mechanic, and have not much time and money with which to experiment, but for all that I take a great interest in every week's *Motor Cycle*, and digest all the information contained, so improving my 'bus, also my knowledge.

EDWARD S. BURSLEM.

## LADY MOTOR CYCLISTS.

Sir,—Knowing that you are interested in lady motor cyclists, I am enclosing a photograph of my wife mounted

Mrs. Jenkins, an enthusiastic rider of a Douglas

on her T.T. Douglas, which she has ridden for the past two years. Her previous mount was a  $2\frac{1}{2}$  h.p. Jap-Royal Ruby, ladies' model, which gave every satisfaction.

ALEC H. JENKINS. Flight-Sgt. R.F.C.

## WHICH TYPE OF HANDLE-BAR LEVER?

A Few Remarks following "The Critics" and Captain Lindsay's expressed Opinion.

CAPT. LINDSAY has expressed his views on the matter of inverted controls in his usual practical way, and the fact that certain readers are entirely satisfied with the control of their machines does not in the least go towards proving that the system employed on the admittedly admirable mounts they quote is superlative. It is generally to be noticed, indeed, that the man who has stuck unwaveringly to any particular make is the first to pour forth the vitriol of sarcasm on designs other than his favourite, whereas he is really the last person on earth who is qualified to express a view.

The fact that, apart from expressing his own views, Capt. Lindsay backed up my statements renders it rather difficult to express an opinion which is entirely adverse to his, but this unhappily must be done. As regards the matter of delicacy of control, I do not think it is of much consequence whether the lever is "inverted" or "open." As a matter of fact, I recently did what Capt. Lindsay suggests, *i.e.*, attached the clutch cable to the left inverted lever of the light-weight I was riding, and found that the arrangement acted perfectly until the wire snapped at the nipple, when, of course, the "cussing" began. Incidentally, the experience demonstrated the vast superiority of the shape of lever employed in the ordinary inverted control to those shaped as in fig. 1—the ordinary outside or "open" type.

### Wide Angle Levers.

On my present mount the handle-bar clutch lever is of the type shown in fig. 1, and grasping the lever naturally one's grip falls between the points A and B on the almost vertical surface. The strength of one's first and second fingers is practically wasted, and in order to overcome this defect in design it is necessary to keep the cable so slack that the lever attains the position shown in dotted lines ere the clutch begins to lift. Only by doing this is delicacy of control possible, and it is conceivable that half the grumbles about stiff handle-bar clutches are chiefly the result of wide angle levers. On one or two Russian

military models I have recently ridden it is necessary entirely to relinquish one's left-hand control of the bars in order to reach down to the "point of leverage," and it must further be borne in mind that one's initial pull is directly upwards as shown by the line of the arrow, so that the leverage is not so great when the lever is at an angle from the bars as when the gripping surface is parallel with the bars. The best leverage, and consequently the greatest delicacy of control is obtained when the point of maximum leverage is moving directly towards the palm of the hand—with the hand in a natural and comfortable position—rather than at a tangent from it, and perfect control can only be obtained by perfect grip which, in turn, is dependent upon retaining possession of the bars by the hold of the thumb and the palm of the hand. Therefore, I think that delicacy depends not on whether the lever

Fig. 1.—An undesirable type of lever. Not till it attains the position indicated by dotted lines is full leverage obtained.

Fig. 2.—A design of lever which gives maximum leverage with the hand in a natural position.

is inverted or "open," but upon the shape of the lever. The advantage of the outside system lies in its simplicity and accessibility, while the inverted, owing to its short centres, invariably snaps the cable at the nipple—a defect not yet touched upon.

Fig. 2 illustrates what can be taken as a desirable type of outside control

lever. Human fingers are not designed to obtain a grip on polished surfaces—in the first place they were probably designed to grip horizontal or almost horizontal branches—and the lever which is to give the best control should be parallel with the bars at the point where delicacy of manipulation (*i.e.*, the clutch slip point) is required. The lever shown is not quite horizontal; its first movement takes up the slack in the cable, and when the work really begins the lever is at the point at which it gives the best leverage and the most comfortable position for the fingers of the rider, *i.e.*, parallel with the hand. So long as sufficient lift is obtained, the shallower the reach the better, and—except in the case of a modern high efficiency flat twin with which type of engine it is necessary to finger the clutch almost in unison with the throttle—"Ixion's" observation that a foot control or a tank lever is preferable to a handle-bar clutch of poor leverage undoubtedly holds good. CHINOOK.

# QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 29, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

## Vibration.

The vibration of the handle-bars of my 2 h.p. four-stroke is terrific. Kindly tell me if a set of new springs would remedy this.—VIBRATION.

We presume you are referring to the fork springs. If the trouble is due to road vibration, new fork springs would be desirable. If, however, it is due to the engine, then all you can do is to have the engine balance checked by a first-class engineer.

## Running on Substitute.

As I have accidentally got hold of a half barrel of turpentine substitute, and am told that I could use it on my 4½ h.p. B.S.A. motor cycle (it is supposed to have a gravity of .785), should I have to make any alteration to my carburettor, or would it be any better if camphor or "Spots" or any of these other preparations were dissolved in it?—LISNALINCHY.

You could run quite well on the preparation mentioned, and you would probably require no further alterations than a warm air intake to your carburettor. It is usually necessary to start on petrol.

## Pillion Riding.

A friend of mine, who is at present incapacitated through an accident which he met with whilst riding a motor cycle on May 28th last, has requested me to write to you and put his case before you for your opinion. My friend was riding out from Barrow, and was on his correct side of the road, going round a curve, when a motor car collided with him. The driver of the car came round the curve towards Barrow, and, instead of keeping to his own side of the road, came straight across the middle of it, and ran into the motor cyclist, breaking his right leg and smashing up the cycle. My friend was travelling about 10 to 12 m.p.h., whilst the car was doing between 20 to 25 m.p.h. The road was about twenty feet wide at the place of the accident. The point I want to know is, seeing that my friend was carrying a lady passenger, on the motor cycle riding pillion, whether he would have a good case against the car owner?—H.W.M.

While we never recommend pillion riding, as we consider it risky on account of the possibility of mishaps of this sort, we do not think the fact that your friend was carrying a passenger should prevent

his succeeding in an action against the driver of the car, for, judging from your statement, the driver of the car was in error, and was the sole cause of the accident, which could not be in any way attributed to the carrying of a passenger.

## Lubricating the Chain.

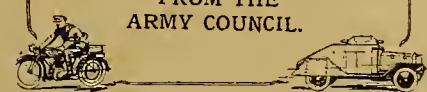

I am anxious about the best way to lubricate my motor cycle chain. It is protected (on the outside only) by an aluminium cover. Would you advise drilling this over the driving wheel from the engine, and screwing a small drip feed into the cover?—W.J.S.

The idea you suggest is a very good one, but we think you can improve on it. Fit a drip lubricator with a wick attachment, so that the wick touches the chain all the time. The wick will prevent an excessive amount of oil reaching the chain, and yet keep it always moist.

## Running on Coal Gas.

(1.) About what size would a bag have to be to hold coal gas to the equivalent of one gallon of gasoline? (2.) Is it possible to get refills for a Presto-light outfit in England?—CANTUCK.

(1.) Messrs. Andrew Barton have made a gas bag for a 2½ h.p. Douglas, 7ft. long by 2ft. in diameter, weighing fully inflated about 6 lb. This is sufficient to take the machine for ten miles. 250 cubic feet of gas are equivalent to one gallon of petrol. (2.) It is, unfortunately, not possible to get refills for Presto-light outfits in this country. The nearest approach we have to this system is the acetylene cylinder, sold by the Acetylene Illuminating Co., Ltd., who are now, like most other firms of this nature, working exclusively on war work.

## Fitting a Magneto.

I propose fitting an early type engine (Clement Garrard) with magneto ignition. The engine sprocket will be fitted on to the timing gear shaft, which rotates in an anti-clockwise direction. Will it be absolutely necessary to have an anti-clockwise magneto fitted, or can a magneto running the other way be used with slight alteration? If so, what alterations are necessary?—A.F.P.

If you are fitting a clockwise magneto it would be necessary to gear direct on to the magneto; that is to say, you would have two pinions, one on the half-time shaft running counter-clockwise, and the other on the magneto shaft running clockwise. If, however, you get hold of a magneto designed to run counter-clockwise, then you can use a chain. A counter-clockwise magneto or vice-versa can be altered by getting a new contact breaker from the makers.

## Cleaning Out the Crank Case.

(1.) To clean out the crank case of my 3½ h.p. 1916 Sunbeam without taking down the engine, is it necessary to add paraffin oil, or is draining through the drain tap sufficient? How much oil should be injected afterwards to lubricate? (2.) When running downhill with throttle lever in closed position, the engine appears to fire in the exhaust. Is this due to the valve springs? (3.) What would be the effect on the running of stretching out the valve springs? (4.) I have a small quantity of petrol purchased before the licences and restrictions came into force. Am I at liberty to use this quantity up, and can I be prosecuted if riding for pleasure it stopped?—W.P.R.

(1.) It is best to wash out the crank case with paraffin after the oil has drained out. Inject about three pumpfuls afterwards. This is explained in "Motor Cycles and How to Manage Them," which can be obtained, price 1s. 10d. post free, from these offices, or from any bookstall, 1s. 6d. (2.) The engine fires when the throttle is apparently closed probably because the throttle does not shut completely. The explosions can be prevented by fitting a switch. (3.) You might get some improvement, as this should cause the valves to close more quickly. Better try a new spring. (4.) You are at liberty to use the petrol you have by you for any purpose you desire.

### Fitting Oversize Tyres.

?

(1.) My motor cycle tyres at present are 28in. x 2in. I find a difficulty in obtaining these. Would 28in x 2 1/2 in. tyres fit the rims properly? (2.) Which, in your opinion, is the better way to stop a motor cycle—to use exhaust valve lifter or magneto switch? I understand the use of the exhaust lifter has a tendency to pit the valves and seatings.—AEON.

(1.) 2 1/2 in. tyres will fit 2in. rims without any difficulty. (2.) Close the throttle, raise the exhaust lifter and apply the brakes. This method of using the exhaust lifter in no way damages the valve or seating. What damages the seating is to use the exhaust lifter as a means of controlling the machine; that is to say, only partially raising it and allowing the engine to fire with the valve not reaching the seating.

### Difficult Starting.

?

I have a 1916 4 1/2 h.p. single, and it is impossible to start it by means of the kick starter. On pushing off it fires, but not easily. The magneto (C.A.V.) has been tested by the makers and found all right. When tested with the plug on cylinder it gives a good spark. I have failed to trace an air leak. I have just cleaned the cylinder and carburetter, but failed to cure this difficult starting. When I bought the machine new in June, 1916, I experienced the same difficulty in starting. I have tried one-point and two-point plugs, with the same result. I prime the cylinder well before trying to start the engine, but I find that the engine is rather heavy to turn round. What is the cause, and how can I remedy the trouble?—LEO.

Difficulty in starting is usually due to air leaks at the carburetter or induction pipe unions. To start easily it is necessary to have a strong mixture and a small quantity of it; therefore any leak in the air slides, round the inlet valve guide, or anywhere else which would cause the mixture to be weakened, would result in bad starting. Try the effect of placing a cloth or felt pad over the air intake when starting up. When flooding, this will absorb the overflow of petrol, and the air drawn through the pad will be very rich with gas. Big single-cylinder engines are often difficult to start.

### Decarbonising.

?

(1.) Having dismantled my engine, I find that inside the pistons is a rather large deposit of carbon. Not being able to remove the piston, having no appliances to take out the gudgeon pins, can I decarbonise by the oxygen process without fear of injuring the small end bearing? (2.) Having the cylinders dismantled, can I with safety decarbonise it by the oxygen process without replacing valves *in situ* or piston?—A.W.

(1.) Having dismantled your engine, and finding carbon deposit inside the piston, we think you can remove this fairly well without taking the piston off the connecting rod, provided you take sufficient care, by wrapping cloths over the crank case orifice, to prevent carbon from

reaching the interior of the engine, and scraping away the deposit. The oxygen process could be used quite successfully without fear of damaging the cylinders or bearings. (2.) You may use the oxygen process on the cylinder alone if you like, but we should advise you to be careful to apply the flame only to the carbon, keeping the flame moving; but there is no object whatever in using an oxygen flame to decarbonise when you have an engine down, as the carbon can be more safely and effectively scraped from the parts covered. The only object in employing the oxygen process is that it can be used without taking the engine down.

### A Mysterious Noise.

?

(1.) My 1915 Scott motor cycle has recently developed a regular metallic clank, which I have traced to the high gear chain apparently catching on something at the crank case end. The cause puzzles me, as the machine has only done, say, 5,000 miles, so it cannot well be sprocket wear, causing the chain to "bottom"; nor can the chain be at fault, for I have fitted a new one, and the trouble still continues. I have also reversed the connecting link, which is the proper size. Is it possible that the whole crankshaft can have shifted to the right; and if so, what is the cure? The crankshaft has never been tampered with. (2.) Also would play in the big end bearing cause the engine to heat? Lately the water has almost boiled on short runs, though everything else seems in order. The carburetter is a B. and B., and has a 42 jet. The timing is one tooth advance of the standard, the exhaust pipe, etc., is clean, the compression is fair, and the oil level is correct. I use Wakefield's Castrol "C."—M 7304.

(1.) We should say that the trouble is in all probability due to a worn sprocket. You say it is unlikely that this should happen in 5,000 miles, but we hardly think so, especially if you were unlucky enough to get hold of a sprocket of rather soft material. If you can obtain a new sprocket and fit it to your machine, we are inclined to think that the trouble will cease. Make sure that the countershaft is in proper alignment by measuring on either side from the edges of the crank case cover plates to the centres of the countershaft. (2.) You need not worry if the water almost boils, provided that it does not actually boil. If the water keeps just on boiling point, the engine will run its best. Probably when the weather gets a little cooler you will not be troubled in this respect. A loose big end would not cause the trouble; two-stroke engines often run splendidly with the bearings badly worn.

### READERS' REPLIES.

#### Difficulty in Starting.

With reference to "G.S.'s" query in your issue of August 16th, page 166, perhaps the following tip may help him. My 1916 B.S.A. (Binks carburetter) behaved in exactly the same manner as his machine, and could only be started by running. I traced the trouble to the difficulty of dropping the exhaust lifter quickly enough to take advantage of

the suction stroke. I always start first kick now. Work kick-starter until compression is felt. Then, with exhaust valve raised, gently turn engine just over top of compression stroke, and return kick-starter to top position. Now, without raising exhaust give a hefty kick, when engine should fire. Of course, the controls are in the usual starting position—spark two-thirds advanced, throttle about two-thirds open, and extra air closed. A small injection may be necessary.—E. HARDMAN.

#### A Two-stroke Defect.

With reference to "J.H.C.'s" query in your issue of August 16th, as it seems to have tried many ways of effecting a means to make his machine run correctly, may I be allowed to offer him a tip with regard to the Dixie magneto? A machine fitted with one of these magnetos would not fire the charge continuously, and no change of speed would result from any movement of the throttle. The general result would appear as a choked jet, although the latter and the plug are in quite good order. Finally, after hours of wasted energy, not forgetting time and temper, it was decided to dismantle the magneto again, and change round the permanent magnets. This was done, and away it went without a misfire or any portion of the machine having to be tuned up. This is caused by residual magnetism in the spindle and bearings acting in such a way as to cause the spark to lose intensity, thus causing misfiring, and I think if "J.H.C." tries this it may overcome his worrying defect.—L. J. HEALE.

#### NO ADDRESS.

If "T.T., Ely," who sent us a query on the 10th August, together with a stamped *unaddressed* envelope, will let us know to what address to send his reply we shall be pleased to give him the information he requires.

## A FRIEND IN MANY A TROUBLE

"HINTS AND TIPS FOR MOTOR CYCLISTS" is compact with useful information for the motor cycle user, and will be found "a handy book to have about you."

It covers all phases of motor cycling—buying, driving, adjustment, equipment, repair, garaging, etc.—and deals with all types of machines, as well as every part of the machine.

THE sixth edition (now on sale) has been thoroughly revised and is right up to date in every respect. A new feature is the inclusion of illustrations showing the working of motor cycle engines, both two-stroke and four-stroke.

There are over 400 separate paragraphs, with distinctive headings and numbers, and five-page index for ease of reference.

Price 1/6 net.

# MISCELLANEOUS ADVERTISEMENTS.

## PRICES.

**ADVERTISEMENTS** in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to **ILIFFE & SONS Ltd.**, and crossed **& Co.**

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4.), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

## NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

## DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

## SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

## MOTOR CYCLES FOR SALE.

# DRUID

## Shock Absorption

—that means perfect handle-bar steadiness which in its turn means perfect security and comfort a wheel—qualities

due to the  
**DRUID**  
dual springs

illustrated, which unitedly alone perfectly absorb all Vertical and Horizontal Shocks, being alone correctly built on scientific lines.

For proof—ask any rider of experience.

A. Drew & Co., Ltd.,  
Leopold St.,  
B'HAM.

The  
**DRUID**  
MARK II.

Made in  
three models,  
Solo or S'car.

INDIANS.—1916 Powerplus combination, sporting coach sidcar, disc wheel, as new, 78 gns.; 1915 T.T., 7-9 h.p., clutch, 39 gns.; 1916 2-stroke Indian, 3-speed, clutch, kick start, as new, 37 gns.; 1914 7-9 h.p. Indian, 2-speed, clutch, kick start, 35 gns.—Rider Troward's, 31 and 78, High St., Hampstead. (D) [7072]

INDIAN, 7-9 h.p., with Swan c.b. sidcar, 1913 spring frame, kick start, new 2-speed gear and foot clutch, triple wind screen and hood (both new), Stewart speedometer, horn, pump, lamps, and spare inner tube, extra seat in sidcar for child, luggage carrier, smart turn-out, in good running order, tyres excellent; £60; seen by appointment only.—S.W.G., 8, Ardwick Rd., N.W.2. [7204]

## Ivy.

IVY, 2-stroke, 2 1/2 h.p., 1915, good tyres, fully equipped, as new throughout; £25.—Advertiser, 156, Gt. Portland St., W.1. [5924]

IVY 2-stroke, 2-speed countershaft gear, late 1916, absolutely as new, specially fitted for paraffin, practically unused; £32.—Axon, 134, Bath St., Rugby. [6982]

## James.

JAMES 2-stroke, 2-speed, 1917, scarcely used; £30.—Smith, 45, Montpelier Rd., Keatish Town. [7087]

COLMORE Depot, 261, Deansgate, Manchester, have in stock complete range of James motor cycles. [0803]

JAMES, 2-stroke, 2-speed, Lucas lamps and horn, leg guards, absolutely as new; £40.—Neale, Littlecote, Solihull. [X4426]

JAMES, 4 1/2 h.p., 1913 model, with 3-speed gear, foot clutch, good condition; £26.—Egles and Co., High St., Acton, W.3. [X4450]

JAMES, 2 1/2 h.p., 1915, 2-stroke, 2 speeds; £31; deferred payments accepted.—Eastern Garage, 418, Romford Rd., Forest Gate, E. [6987]

JAMES, 2 1/2 h.p., 1916, 2-stroke, 2 speeds, lamps, and horn; £36; deferred payments accepted.—Eastern Garage, 418, Romford Rd., Forest Gate, E. [6988]

1913 James Combination, waterproof Bosch, chain drive, countershaft 2-speed gear, coach-built body; £56/10.—Motor Exchange, Horton St., Halifax. [7051]

4 1/2 h.p. James and Sidcar (1916), only done 500 miles, 41 splendid condition, lamps, Klaxon horn, tools, etc.; £65.—Harvey, 25, Westbourne Rd., Walsall. [X4500]

1917 James, 4 1/2 h.p., solo, 3-speed, kick starter, run 100 miles; £55; purchased July. Phone: Avenue 2900.—14, Spital Sq., Bishopsgate, E.1. [7279]

RIDER TROWARD'S, 31 and 78, High St., Hampstead.—1917 James de Luxe combination, Lucas dynamo lighting; cost £103; run 1,000 miles, 79 gns. (D) [7075]

JAMES 1914 3 1/2 h.p. Twin, T.T., 3-speed, clutch, kick starter, very fast, wonderful climber, good condition, all accessories; £53.—Brown, St. Martin's House, Hereford. [X4494]

JAMES, 1914, 4 1/2 h.p., 3-speed countershaft gear and clutch, mechanical condition sound, with sporting coachbuilt sidcar; £42.—Pay, Wheatash Rd., Addlestone. [7159]

JAMES, 2 1/2 h.p., 2-stroke, 2 speeds, 1915-16 model, very little wear, accessories, will run on half paraffin; £29, or nearest.—Ward, 7, Herndon Rd., Wandsworth. [7150]

JAMES 4 1/2 h.p. 1914 Combination (coachbuilt), 3-speed countershaft gear, speedometer, and horn; £44; deferred payments accepted.—Eastern Garage, 418, Romford Rd., Forest Gate, E. [6986]

JAMES Combination, late 1916, 4 1/2 h.p., 3-speed, all chain drive, only ridden 500 miles, all accessories, including two new lamps; a great bargain, £65.—Woodward, 25, Silvertown Rd., Fulham Palace Rd., Hammer-smith, London. [X4308]

1917 3 1/2 h.p. Twin James, 3-speed, and hand clutch, lamps and horn, mileage only 1,200, in perfect order throughout, and running like clockwork; £60, or near offer; cost £72; owner going abroad; could probably arrange ride 50 miles see bona fide purchaser.—Smith, Rackenford Lodge, Weybridge. [7013]

## J.A.P.

4 h.p. 1916 J.A.P., 2-speed, Kick starter, all chain, sidcar; £45.—Digby, Mersea, Essex. [7109]

4 h.p. J.A.P. and Sidcar, N.S.U. gear, Dunlops, splendid condition; £26/10.—Laughlin, 213, Rye Lane, Peckham. [6946]

## J.H.

J.H., 2-speed, new; £35/14; extended payments or exchange.—Service Co., 292, High Holborn, London. [X4152]

J.H., 1917, new, 2 1/2 h.p., 2-speed, 2-stroke; 42 gns.—W. and H. Motor Co., Ltd., 287, Deansgate, Manchester. [7192]

LATE 1916 J.H., 2-stroke Villiers, absolutely perfect, and new condition, full T.T., spare belt, silencer, etc.; cheap, £20.—Jeannings, 9, Meadow, Gidea Park, Romford. [7267]

SELECTION FROM 150 MACHINES IN STOCK :  
New 1917 Models.

ALLDAYS ALLEN, 2-speed, 2-stroke	40 gns.
COVENTRY EAGLE, 2-speed, 2-stroke	40 gns.
JAMES, 2-speed, 2-stroke	40 gns.
JAMES, 3 1/2 h.p. twin, 3-speed	£69 10
JAMES, 4 1/2 h.p. single, 3-speed	£69 10
NEW IMPERIAL, J.A.P., 2-speed	40 gns.
ROVER, 3 1/2 h.p., T.T., Philipson	—
ROVER, 3 1/2 h.p., 3-speed	—
ROYAL RUBY, 4 h.p. J.A.P., Sturmer	69 gns.

## Second-hand Combinations.

BOUNDS J.A.P., 1915, 8 h.p., 3-speed, coachbuilt	59 gns.
B.S.A., 1916, chain-drive, coachbuilt	62 gns.
DOUGLAS, 4 h.p., 3-sp., clutch, kick-start, coachbuilt	59 gns.
ENFIELD, 1917, de Luxe Combination, Lucas dynamo lighting, hood, screen, luggage grid; cost £120	92 gns.
EXCELSIOR (American), 1915, de Luxe coachbuilt Combination, 7-9 h.p., 3-sp., dynamo lighting, speedometer, etc.	69 gns.
HARLEY-DAVIDSON, 1915, standard 7-9 h.p. Combination	65 gns.
HARLEY-DAVIDSON, 1915, dynamo lighting, 7-9 h.p. Combination	69 gns.
HARLEY-DAVIDSON, 1916, standard Com.	82 gns.
HARLEY-DAVIDSON, 1916, dynamo lighting Combination	86 gns.
HARLEY-DAVIDSON, 1917, dynamo lighting Combination	119 gns.
INDIAN, 1915, 7-9 h.p. coachbuilt Comb.	45 gns.
INDIAN, 1916, Powerplus sporting Com.	78 gns.
JAMES, 1917, de Luxe coachbuilt Combination, Lucas dynamo lighting, electric horn, as new; cost £103	79 gns.
PREMIER, 1914, 3 1/2 h.p., 3-speed, coach Sidcar	37 gns.
PREMIER, 1915, 7-9 h.p., 3-speed, countershaft, 30 gns.; Sidcar	45 gns.
SCOTT, 1915, coach Combination, as new	55 gns.
TRIUMPH, 1914, 4 h.p., 3-speed, 1916 coach Sidcar	48 gns.

## Solo Mounts.

ALLEN, 1916, 2-speed	27 gns.
BROUGH, 1916, 3 1/2 h.p. twin, 3-speed, Sturmer countershaft	59 gns.
B.S.A., 1913, T.T., 2-speed, clutch	27 gns.
CALCOT, 1914, 2 1/2 h.p., 3-speed, clutch	22 gns.
CALTHORPE, 1915, 2 1/2 h.p. J.A.P., Enfield gears	24 gns.
DOUGLAS, 1913, T.T., 2-speed	29 gns.
DOUGLAS, 1914, T.T., 2-speed	34 gns.
ENFIELD, 1916, 2-speed, 2-stroke	27 gns.
HARLEY-DAVIDSON, 1915, T.T., 7-9 h.p., 3-speed	54 gns.
HUMBER, 1913, 3 1/2 h.p., 2-speed	22 gns.
IVY, 1915, 2-speed, 2-stroke	24 gns.
INDIAN, 1914, 7-9 h.p., 2-speed, clutch, kick-start	35 gns.
INDIAN, 1915, T.T., 7-9 h.p., clutch	39 gns.
JAMES, 1914, 4 1/2 h.p., 3-speed, clutch, k/s	39 gns.
LEVIS, 1916, as new	24 gns.
METRO, 1916, 2-stroke, sloping tank	22 gns.
NEW HUDSON, 1914, 2 1/2 h.p., 3-sp., clutch, kick-start	25 gns.
NORTON, 1914, T.T., Philipson	29 gns.
NORTON, 1915, T.T., Philipson	32 gns.
O.K.-JUNIOR, 1915, 2-speed	17 gns.
O.K.-J.A.P., 1916, 2-speed	23 gns.
RADCO, 1916, 2-stroke	22 gns.
RUDGE, 1912, 3 1/2 h.p., 2-speed, clutch	17 gns.
RUDGE-MULTI, 1913	24 gns.
RUDGE-MULTI, 1914, T.T. model	27 gns.
RUDGE-MULTI, 1917, as new	49 gns.

RIDER TROWARD & Co.  
31 & 78, High St., Hampstead.

Phone: 5392. Open 8 p.m. and Sundays.  
1 minute Tube.

All machines can be sent on  
"The Motor Cycle" Deposit System.

## MOTOR CYCLES FOR SALE.

## Kerry.

KERRY, 2 1/2 h.p., spring forks, less mag.; £4/10. 816, Harrow Rd., London. [720]

## Lagonda.

4 h.p. Lagonda, free engine, Bosch mag., Amac ca buretter, spring forks; bargain, £16/10.—91, Kings Rd., Peckham. [704]

## Levis.

LEVIS, used 3 weeks only; £26; full equipment.—65 Rosendale Rd., Dulwich. [727]

2 1/2 h.p. Levis, practically new, full accessories; £19/10 lowest.—Morgan, 60, Kingscourt Rd., Streatham [703]

COLMORE Depots, Birmingham and Leicester, delivery of all models of Levis motor cycles from stock. [080]

LEVIS, 2 1/2 h.p., 1915, 2-stroke, head lamp, generator rear lamp, good tyres, fully equipped; bargain, £2.—Advertiser, 156, Gt. Portland St., W. [660]

LEVIS, late 1915, 2 1/2 h.p., new tyres, lamps, horn tools, etc., condition as new; £22. Smith, 11 Haverstock Hill, opposite Chalk Farm Tube Station. [720]

LEVIS Model E, 2-speed, 2 1/2 h.p., £47/10; also Poplar model at £32; also 1914 Baby model, 2 1/2 h.p. at £23/10.—Lamb's, 151, High St., Walthamstow, or 50, High Rd., Wood Green, N. [724]

LEVIS 2 1/2 h.p. Popular Lightweight, 2-speed, chain and belt drive, rubber studded tyres, brand new in stock for immediate delivery; reduced price, £44. Mebes and Mebes, 156, Gt. Portland St., W.1. [692]

## Lincoln-Elk.

RIDER TROWARD'S, 31 and 78, High St., Hampstead.—Lincoln-Elk, 1913, 3 1/2 h.p., variable gear waterproof Bosch, in good order; 19 gns. (D) [708]

LINCOLN-ELK 3 1/2 h.p. Motor Cycle and sidcar, Bosch, 2-speed, F.E., handle starting in perfect condition; £18, or near offer.—19, Nigel Rd., Peckham [712]

## Martin.

4 1/2 h.p. Martin-Jap Racing Model, o.v.; £32; exchnge for touring model.—Pemb-Rhos, The Common Weybridge. [X446]

## Matchless.

MATCHLESS Motor Cycles; no quicker delivery of reliable than from Colmore Depots. [088]

MATCHLESS 8 h.p. Combination, 2 speeds, good condition; £40.—Coombs, Gunter Garage, Gunter Grove, Chelsea. [714]

MATCHLESS, 1917, 8 h.p., war model combination spare wheel.—A. H. Price, Mount Pleasant Bradford-on-Avon. [717]

MATCHLESS 1915, 8 h.p. Twin J.A.P., 2-speed combination, new sidecar, Jones speedometer, P. and H. lamp and rear; £70.—B. S. Roy, Barnham Marks Norfolk. [X438]

MATCHLESS, late 1915, 7 h.p. M.A.G. coachbuilt sidcar, just repainted black and gold line, as M. Sunbeam, all accessories; £85.—Cass's Motor Mart, Warren St., Euston Rd., W.1. Museum 623. [582]

MATCHLESS-J.A.P. 8 h.p. 1914 Combination, 2 speeds, free engine, kick start, fitted for colt stitute, very fast and powerful, recently overhauled £42, no offers.—65, Ford Rd., Catford, S.E.6. [715]

MATCHLESS Combination, 1915, M.A.G. engine, 2 speed, kick start, hood, screen, 3 lamps, luggage carrier, perfect order; price 70 gns.; seen evenings 6 o'clock.—254, Gt. College St., Camden Town, N.W. [713]

MATCHLESS 1917 Combination, 8 h.p., 3-speed clutch, and kick starter, detachable wheels, including spare wheel, new; £120; extended payments or exchange.—Service Co., 292, High Holborn, London. [X415]

1913 Matchless-Jap, 4 h.p., 2 speeds and free engine Bosch waterproof, drip feed, all accessories, gallons petrol; £23, or exchange for modern combination and cash adjustment.—B. Sharman, 52, Pepys Rd., New Cross, S.E.14. [703]

MATCHLESS, 1915, 7 h.p. M.A.G. engine, 3-speed hood, wind screen, speedometer, lamps, and horn £89/10; also 1914 8 h.p. J.A.P. model, just in, price on application.—Lamb's, 151, High St., Walthamstow, or 50, High Rd., Wood Green, N. [724]

MATCHLESS, 7-9 h.p., 3-speed countershaft gear clutch, and kick starter, complete with two £3/18; F.R.S. lamp sets, electric horn and rear light, speedometer, trip record, new back and front tyres, only used Sundays, smartest lot on the road; £70.—Cox, 7, Chilton Hill, New Cross, S.E.14. [712]

## Minerva.

1 1/2 h.p. Minerva, just enamelled, replated, new 26x2 1/2 tyre, new lamp, guaranteed; £9/9.—1 Norwood Crescent, Southport. [X430]

## Motococche.

MOTOSACOCHE, fitted with mag., in fine running order; £10.—Merrick's Stores, 174, Listerhill Rd. Bradford. [701]

## New Hudson.

1913 New Hudson, 3 1/2 h.p., 3-speed, clutch, lamp horn, etc.; great bargain, £27.—Trutt, Fen View, Skewen. [X442]

### The Motor Cyclist Mechanic.

**I**T is not for a moment suggested that the average modern motor cycle needs an engineer to keep it in running order (in fact, we shall shortly show that the reverse is the case), but it is most essential that the motor cycle rider should have a thorough knowledge of his machine and be capable of doing all running repairs. A good many motor cyclists are handy men and eventually become fairly skilful in the use of tools—a most desirable accomplishment. But it is true—how true we only learned comparatively recently—that many motor cyclists cover thousands of miles with practically no mechanical knowledge at all. The machine takes its owner out and home again with monotonous regularity, and when it ceases to pull well, or fails to run at all, it is taken to the garage, put in order, its owner cheerfully pays the bill and continues his happy-go-lucky career.

That numerous such riders exist was forcibly brought to our notice when the staff of *The Motor Cycle* examined recruits for the technical branches of the Army. Such people could not answer the simplest questions concerning the working of their machines, even though they had been riding two or three years. At the present time more than ever the motor cyclist should be capable of doing all he can for himself. He should read and study all the excellent handbooks on the subject, fit up his shed as a workshop, and by dint of the book and practice learn the art of valve grinding, filing, soldering, and riveting, so that he may be independent of the local man, who, nowadays, if he is in a small way, is short staffed; or, if in a large way, is busy with munition work. To rig up a motor cycle shed as a workshop is not necessarily an expensive matter, and the tools required need not be numerous, but it is most desirable that the place should be well lighted.

In spite of the reliability of the modern machine, some time or other trouble is bound to occur, and so it is wise to have everything requisite

to getting on the move again—not only the necessary tools and spares, but the knowledge to use them, and this is only acquired by the man who thoroughly understands his machine.

Motor cycle riding is a healthful pastime in more senses than one, as it not only stimulates and benefits the body, but it exercises the brain by bringing out skill in manipulation and in teaching the owner how to use his hands.

### The Best Metal for Cylinders.

**A** MOST interesting and important subject was discussed in *The Autocar* nearly a month ago, viz., the effect that the material used in the construction of cylinders has upon engine friction. It has been pointed out in our columns on previous occasions—to wit, by Mr. J. L. Norton, on January 11th of this year—that the friction, which takes place between the piston rings and the cylinder walls, accounts for the greatest frictional loss in an engine; moreover, static friction, which is far more serious than the friction between moving bodies, comes into force at each end of every stroke. This being the case, every improvement in the working surface of the cylinder must be of the greatest value.

It is pointed out, with truth, that it is not so much the surface which may be put on a highly finished engine, though naturally that should be as perfect as it is possible to make it, as the surface which the cylinder takes in use. It is well-known that many cylinders after use have a highly polished glass-like interior; this, of course, means a minimum of friction, while others attain a condition far less perfect. Obviously, these differences must be due to the varying qualities and composition of the cylinder metals.

We should much like to see experiments carried out with cast iron of different quality and composition, as well as with steel and aluminium, with a view to finding the most suitable materials for this important purpose.

# IDEAS: Useful and Ingenious.

Sydney R. Jones

## A TIP FOR P. & M. RIDERS.

THE sketch shows a rather useful and simple tip for P. and M. owners. I was riding recently in one of the R.F.C. sidecars, and noticed that the spring forks were fitted with two extra Terry springs hooked on, one on each side in the manner shown. I asked the driver whether they were advantageous, and he assured me that they were a very great improvement, adding materially to the comfort of the machine, and entirely preventing the forks from "clashing," which they are rather apt to do on these appalling roads. I thought perhaps any of your readers who happen to be P. and M. riders might care to try this tip, because the springs are so cheap and easily fitted, and also look exceedingly neat. I must apologise if the drawing is inaccurate, as it is almost entirely done from memory.

I was never a P. and M. owner myself, though I have owned fifteen different machines; in fact, I have only actually ridden a P. and M. on two occasions, but I must take this opportunity of expressing my admiration of the way in which this make of machine stands up

A useful idea for riders of motor cycles, on very rough roads, is the fitting of two extra springs on the forks.

to the rough work out here; and every one of the despatch riders whom I have questioned on the merits of the machine has had nothing but praise for it. I suppose I must add to this the usual disclaimer.—W. A. N. SMITH, Lt. (B.E.F.).

## A TOOL FOR REMOVING A TIMING PINION.

MANY owners of J.A.P.-engined motor cycles find it necessary at some time or other to remove the small timing pinion from the engine shaft, and a hint or two as to how this may be done will undoubtedly be of interest to them.

The pinion is secured to the shaft by being screwed on with a left-hand thread, and to facilitate its removal a

special tool is required. As, owing to the Prohibition Order, this tool cannot be purchased, an excellent substitute may be made in the following manner: A steel tube, almost the size of the

pinion, should be obtained, and in one end of it a tommy bar should be inserted so that it is a driving fit. Next, a number of steel pegs should be inserted at intervals round the tube and brazed or screwed into position, corresponding with the gaps between the teeth, and if sufficient force is exerted the wheel may be removed without fear of damage. Attempting to hammer it off with the aid of a brass punch may result in the teeth being chipped or broken.

A tool for removing a timing pinion.

pinion, should be obtained, and in one end of it a tommy bar should be inserted so that it is a driving fit. Next, a number of steel pegs should be inserted at intervals round the tube and brazed or screwed into position, corresponding with the gaps between the teeth, and if sufficient force is exerted the wheel may be removed without fear of damage. Attempting to hammer it off with the aid of a brass punch may result in the teeth being chipped or broken.

## HOW TO CARRY A BELT.

I AM sending an idea which may be useful to D.R.'s generally. It is a device for carrying the spare belt, and has been used by our Divisional Section for a long time. The spare belt is generally hung in any old place, sometimes coiled round the tank or fastened to the carrier by bits of wire, seldom looking a tidy or workmanlike job. The sketch, I think, explains all that is

A simple method of making a belt case.

required. The discs are cut from oil drums, preferably using the bottom plate, which is of a stout gauge. "Black box" clips fasten the back plate to the carrier stays. The centre bolt and wing nut can usually be obtained from the "Column," or perhaps the Q.M.S. may stock them for the Barrow drum universal. If a "posh" effect is desired a thick brass wire may be sweated to the edge of the top plate or a strip soldered on the underside to enclose the belt entirely. The belt should be coiled and wired before placing in the holder.—SOUJIER D'OR.

## A COOLING FAN.

A GOOD deal has been written about internal cooling of the engine; but why not try external cooling, as we have done? An 8in. fan was fixed on the left-hand side of the engine, fastened on by the two nuts that hold the cylinder down. Its power is conveyed from a pulley fixed on to the flange of the engine pulley to another fitted on the bracket as shown in the drawing. A half-inch

leather belt suffices to put this 8in. fan at about 2,000 revolutions per minute, according to how fast the engine is travelling. I have found the device to be very efficient in cooling the engine, and by it the power is retained. Recently I gave this idea a severe test by going on a tour of 18 miles into the heart of Wales.

A simple method of fixing a fan to assist cooling the engine.

It gave every satisfaction, taking some hills on top gear that I should have had to change down on had I not had the little fan. My machine is a 3½ h.p. two-speed Humber, and the device has cured my greatest trouble—knocking on hills. It is quite compact, is unobtrusive, and a unquestioned boon.—H. J. WAKEFIELD Birmingham.

## TO SECURE SCREWS.

THE set pins holding the rear wheel stands of many machines are a source of constant irritation through coming unscrewed. This can be remedied by seccotining the thread, taking care to keep the seccotine from the cone washer and set pin head.—L. QUINTON.

# Occasional Comments by "Ixion"

## An Experiment.

IF I had time, money, and the necessary resources, I should like to build a single experimental engine. Steps would first be taken to equalise its front and rear cooling as far as possible. Then the best metals and the best constructional system would be employed to radiate away as much of the waste heat as possible. It might have, for example, an aluminium alloy piston; a steel cylinder barrel, machined to a dead even thickness throughout; copper fins secured round the steel barrel; possibly a cast aluminium combustion head, with seatings for the overhead valves embodied in the casting. I should expect such an engine to prove itself an astonishingly good hill-climber on a normal top gear ratio; to carbonise very, very slowly; to be almost konkproof; and to register a gratifying petrol consumption.

## Commercialising the New Type.

THE expense of such an engine might prove prohibitive when it came to manufacture. I am an utter ignoramus at costing, but I fancy I have heard that aluminium now costs about £225 per ton, and copper is not exactly cheap. Granville Bradshaw managed to sell his twin, with cylinders machined from the solid steel ingot, at £63 before the war, and presumably the waste metal cost him little more than the combined cost of dud iron castings and more complex machining jobs cost a more orthodox designer. Still, where there's a will there's a way, and I shall never believe that the discoveries in respect of air-cooling which aviation has brought us will not be reflected pretty accurately in post-war motor cycle practice. The A.B.C., for example, in pre-war days struck one as a lovely job, until one took its engine down and handled the great clumsy cast iron cylinder heads. They did not strike us as clumsy then, for they were probably as good as anything in that line which the world's foundries had turned out in those days; but when you have seen a section of the cylinder head of the latest 260 h.p. Mercedes, 1914 cast iron work seems a wash-out: and some of our own modern engines, not to speak of those of France, can give that Merc. head a long start.

## Heat Distortions.

RESEARCH in connection with air-cooled aero engines during the war has proved that large air-cooled cylinders of cast iron distort very badly in the air, and one wonders how far this justifies the deduction that small air-cooled cylinders of cast iron distort very badly on the road or the track. The circumstances under which the two types of engine work are not, of course, strictly parallel. The aero engine is perpetually working at full throttle, or very near it; the motor cycle engine is throttled down to about half its power output for most of its working life. The aero engine has a cooling draught of about 80-120 m.p.h. velocity on its front, and nothing in the way of a breeze on its stern, unless special cowling is arranged

for it. The motor cycle engine receives a 30 m.p.h. draught on its face and no breeze at all on its rear, except what gets round the corner. Nevertheless, a little consideration suggests that the motor cycle engine of pre-war type suffers quite appreciably from distortion, even though its fore and aft temperatures may not show quite such a divergency as those of an aero engine.

## Primitive Aero Engines.

THE early air-cooled aero engines distorted so badly that they had no compression left worth mentioning after a short spell of hard work. They glowed like red hot coals when dusk came on. They burnt out valves galore. Their petrol consumption was truly frightful, seeing that compression leaks admitted air and produced such a slow-burning mixture that a large proportion of the charge could get no real resistance to push against; that the compression stroke became in part an exhaust stroke, thrusting unburnt gas out through undesired apertures and clearances; and they mopped up oil incredibly, as they relied on it so much for cooling.

## How they were Improved.

DISTORTION was gradually brought under control, if not wholly eliminated, by a variety of dodges. Peculiar piston rings were employed to follow up distortion. The contrast between a 100 m.p.h. blast on the engine's face and a zero blast on the back of its neck was evened up by cowling. Less expansive metals were employed for the cylinders. More radiative metals came into vogue for the piston. Novel constructional methods arose for eliminating all the blobs of thick metal which used to disport themselves here and there in the engine and render even expansion impossible. So to-day we can construct colossal air-cooled cylinders, which are just about as compression tight at the end of a three hours' flight as they were when they left the hands of a first-class factory or squadron tester.

## What about the Motor Cycle Engine?

I SHOULD say that most thoughtful motor cyclists are quite convinced that distortion is at the bottom of konking, though they may not be able to work out the details. We all notice that when we get our engines really hot, either after prolonged hill work with a sidecar or scrapping solo on low gear, or after illegal and sustained speed on the flat, our engines are uncommonly easy to turn over; there is precious little resistance to the upstroke of the piston, and in extreme cases you can easily push off without lifting the exhaust valve. Indeed, I know some riders who say that those konks which are accompanied by heat are due to a slow burning mixture taking up all the engine clearances rather deliberately, and that you can "run off" the konk if only you can get speed up, simply because the weaker mixture suits the faster speed. Anyhow, it will be interesting to see how experimental engines made on aero principles behave.

## A WAR-TIME OVERHAUL.

Many machines being laid up on account of petrol shortage, a few hints on the matter of effecting a thorough overhaul will be acceptable.

**E**ARLY this year I became painfully aware that my sidecar combination had lost its pristine vim, and the sarcastic remarks of some supposed friends as to its appearance strengthened my determination to have it thoroughly overhauled at the earliest opportunity. It was, however, quite another matter to get that determination carried into effect. The makers could not undertake the work, and all firms of repute being engaged with Government or controlled work, the only alternative was to tackle the job myself. This sounded very nice until a list of the various requirements and operations to be undertaken were carefully drawn up and examined; then the magnitude of the task, to one who has no workshop available, was realised (especially as there is no motor shed attached to my residence, and the combination has to be garaged about a quarter of a mile away). I had intended to do the work during the winter and early spring, but it was postponed time after time, as the prospect of working in an Arctic atmosphere was not alluring, and the shed at my disposal was not heated. A rough idea of the work in contemplation will not be out of place.

**Machine.**—A thorough overhaul; the frame to be enamelled and a few parts plated.

**Engine.**—Owing to one of the flywheels having worked slightly loose, and the machine having been run for some distance in that condition, the taper hole through which the crank pin passes had become slightly oval. Thus it was impossible to lock up the flywheel dead true, and it was decided to have it rebored and a special crank pin made and fitted. The machine having covered over 25,000 miles, the cylinders had worn oval, and new ones had to be obtained. The lapping out of old cylinders and fitting new pistons—which, of course, would not be standard size—was thought of, but in working out the cost the difference was so slight that the former course was decided on. The other repairs that might be necessary could not be ascertained until all was dismantled, cleaned, and a thorough examination made.

With regard to the sidecar, the renovation of this was to be of a thorough order. The upholstery was worn out, the paintwork badly chipped and scratched, the framework rusted up, the hood and apron were

in holes and torn, and the framework of the hood broken.

The size of the shed was only 8ft. x 6ft. 6in.—just large enough to house the outfit comfortably, but very much too small when all was dismantled. It was decided to take off the sidecar body, leaving the work in connection with it to be done at the house, where a cupboard just large enough to take the body was available. I intended to do the main part of the work on the sidecar body on the lawn, when the weather was suitable.

Previous to dismantling, the available supply of tools had been taken to the garage and a temporary bench fitted up with a 4in. vice and a small bench drill. The accumulation of tools was fairly extensive, as for some years past I have been in the habit of doing all possible repairs myself, starting on this basis: I used to calculate roughly the cost of a certain repair; if I considered it possible to do that repair myself, provided I had the necessary implements, I spent the estimated cost of repairs on the tools, and after having done it, I had the tools for future use.

In this way I became possessed of a very useful set. These were all transferred from the house to the garage, together with two gallons of paraffin for cleaning purposes, plenty of old

rags, sandpaper, emery cloth, a number of small cardboard boxes and round tins for storing nuts, bolts, balls from bearings, and the many small parts. A box of odds and ends of nails and screw eyes on which to hang parts, etc., was useful for driving and screwing into the walls.

The preparation of the shed and collection of everything necessary took some time, but this was saved later by having any particular tool available when required.

Everything being ready, a start was made and the dismantling process proceeded.

One thing, it ought to be mentioned, must be obtained, and that is an efficient covering for one's clothes; otherwise the cost would be materially increased by having to purchase various new garments. Engineers' brown overalls give efficient protection, but it is advisable to change into an old suit, especially during the dismantling and cleaning process.

The small workshop in which the work was done. It measures only 8ft. x 6ft. 6in.

# A War-time Overhaul.—

The stripping is done in the usual way, all nuts, bolts, washers, and other small parts being placed in a tin (2 lb. golden syrup tin for preference) in which a few tiny holes have been punched in the bottom. This can be placed in the pail containing paraffin, and, after soaking, a good shake will remove all the oil and dirt, the paraffin draining out at the bottom. This is a very effective way of cleaning small parts. Afterwards these are dried with a cloth and put away in small boxes for the assembling period. If it is intended to have any replated, they should be sorted and strung on thin copper wire ready for the platers.

## Importance of Thorough Cleaning.

Too much attention cannot be given to the cleaning. Paraffin and stiff brushes of various shapes should be freely used. A most useful recent purchase was a brazing brush about 6in. x 1 1/4 in. wide; this had steel bristles, which removed all kinds of dirt, oil, and loose enamel in a very expeditious manner, and it cost only about a shilling.

The cleaning of the machine, when dismantled, with the careful and minute examination of the whole, took the writer just a fortnight. This, of course, means the spare time after six o'clock in the evening, Saturday afternoon, and one other whole day each week. It is only then that the necessary replacements can be ascertained, and the repairs to those that it is not intended to renew decided on.

Remembering the mileage this machine had done, the replacements necessary were less than anticipated. The cylinders, as already stated, were badly worn, and new ones were decided on in preference to lapping out and fitting new pistons. The disadvantage of the latter course would be that the pistons, gudgeon pins, and bushes would not be standard, and future replacements would have to be specially made. New gudgeon pins and bushes for the small ends of the connecting rods, a new crank pin and rollers for the big end, were found necessary. These were the total replacements for the engine, and the parts were ordered at once.

**Gear Box.**—A close and thorough examination revealed the interior to be in perfect condition, and the cover was replaced without disturbing anything.

The Clyno outfit after being overhauled and re-enamelled.

**Gear Levers.**—The internal and external gear levers on the gear box are fitted together on a square, locked with a nut and split pin. The square portion had worn considerably owing, no doubt, to its being used when slack, with the result that there was now considerable play. This made it difficult to get the gears home, and sometimes they jumped out of their own accord. The thread of the bolt had stripped in the

effort to tighten the nut sufficiently to make it hold. First the square on the internal lever was filed up dead true, and the same done on the receiving portion of the external lever. The latter was now a slacker fit than before, probably 1/32 in. all round. To take up this slack it was decided to pack up the internal portion by soldering a strip of sheet steel all round. Firstly, a strip of steel the desired thickness

was cut and tinned with solder, the square portion of the lever being treated in the same manner. The strip was then shaped and put round the square, the other lever being driven into position with a hammer. An Imp blow-lamp was then put on until the solder was well run in, when it was allowed to cool. The external lever was then driven off and the job lightly touched up with a file, the result being a perfect and substantial fit. The stripped screw being 5/16 in., a 1/4 in. Whitworth die was run down and a suitable nut fitted, while in the place of a split pin a strong spring washer was used. This made quite a satisfactory job, and completed the repairs to the gear box, which was put aside till wanted for assembling.

A mudguard was repaired by riveting and soldering a plate on the inside of the valance.

Attention was next given to the metal-to-metal plate clutch. This was dismantled and the plates withdrawn, care being taken not to disarrange the order in which they were taken out. The reason for this is that the respective steel and phosphor bronze plates adapt themselves to their neighbours and work much more sweetly if left in their original positions. To clean them, it is only necessary to tie them loosely together with string or thin copper wire and

immerse them in clean paraffin, leaving them to soak. Before removing the clutch from the mainshaft it was noticed that it was not fitting tightly on to the shaft, and though the nut was pulled up no improvement could be obtained. The main gearshaft was withdrawn, and after some time had been spent in ascertaining the cause, it was found that a shoulder required slightly filing away to allow the clutchshaft to go

**A War-time Overhaul.—**

further on to the main gearshaft; when this was done the slackness disappeared. The push rod and operating pin showed signs of wear. New ones were made out of mild steel, and when finished were case-hardened. The clutch cable was badly frayed, and a new one obtained from the makers.

The chains and sprockets were in excellent condition, and beyond a thorough cleaning did not require attention, with the exception of replacing one roller on the front chain.

**Overhauling Brakes and Wheels.**

The front brake was in good condition and needed no repairs, but the back—an internal expanding working inside the drum of the back driving sprocket—was, judging from its recent behaviour, suffering from a worn-out Ferodo lining. When thoroughly cleaned and inspected, however, this was not found to be the case, the lining being at least  $\frac{3}{16}$  in. thick, and perfectly even all round. The unsatisfactory working was caused by the rivets projecting slightly above the lining, and attention to these cured the defective operation.

The wheels were expected to require a certain amount of attention, as I had been aware for some time past that all was not right with the bearings, not that they compared unfavourably with those of the numerous other machines I have possessed—in fact, rather the contrary, the bearings themselves standing up well, but the locking device would not stand the severe side thrusts imposed by a heavy sidecar. I have not in my long experience found any front wheel ball bearing that would stand for more than one month without attention when a heavy sidecar is used. It was desirable, therefore, to remedy this defect, and the only solution that suggested itself was the fitting of tapered roller bearings to take up the end thrust. Timken taper roller bearings, made by the Electric Ordnance and Accessories Co., were obtained, and the remarkable part of it was that these fitted the hub perfectly (after the old ball bearings and cones had been removed) without any material alteration to the original hub. This was exceedingly fortunate, and materially assisted in eliminating the trouble of an unsatisfactory front wheel bearing, and as the wheels are interchangeable both were treated.

**Rims.**—A considerable amount of rust had accumulated in the bead of the rims. This was removed with the aid of a screwdriver, file, and broken hack-saw blade, and finished off with a thorough scrubbing with the wire brazing brush.

**Forks.**—These were completely dismantled, and being in good condition required no renewals.

**Mudguards.**—The mudguards had suffered somewhat from rust, and both were broken almost across, the back one so badly that a new one was obtained. The front was cracked in the centre, between the forks, but, apart from being rusted inside, was in fair condition. It was decided to try and repair this by

soldering and riveting a piece on either side. First the guard was cleaned inside and out by removing all enamel and rust. Old sheet metal is difficult to solder unless thoroughly clean, and a bad repair is worse than no repair at all. Having thoroughly cleaned the metal, it was tinned with solder, the flux used being "killed" spirits of salts into which a small quantity of sal ammoniac had been dissolved. My experience with the various compound preparations sold for soldering is that they do not come up to the old-fashioned "spirit" for satisfactory results. For mending and strengthening the broken portion I used a piece cut from the scrapped mudguard, as I then had a beaded edge at the bottom which would add strength to the repair. This was cut to size, cleaned, and tinned with solder. The small blow-lamp came in very useful here, as, after tinning, the work was again heated and the superfluous solder wiped off with a cloth. The reason for this was that if there is any quantity of solder left on the metal you cannot rivet the two plates closely together and therefore secure a good joint. The strengthening plate and mudguard were then clamped together and a hole drilled through the two. On either side of the crack a small  $\frac{1}{8}$  in. copper rivet a quarter of an inch long was inserted, a copper washer being used on the inside and the two well riveted together. Thus fixed, it was quite easy to drill the necessary number of holes and rivet the two members together. The manoeuvre was repeated on the opposite side of the mudguard, and a very strong repair effected. This, however, did not complete the job, as the blow-lamp was again brought into use. The riveted portion was again heated and more solder run in, which would adhere to the already tinned plates, very much strengthening the repair. A little solder was also melted into the crack on the outside of the mudguard, and when cleaned up with a file the crack was hardly visible.

**Care of Control Wires.**

Nothing is more annoying to a driver than the inability to control an engine easily in consequence of defective or frayed Bowden wires. Possibly no part of the machine has less attention than the latter, with the result that they are neglected until they either break or refuse to move in their casings. Periodical attention will ensure the perfect working of these almost indispensable fittings. The machine in question had been from time to time examined, and when possible thin oil run down the casings and the exposed parts greased. When dismantled, every wire with the exception of the exhaust lifter was found to be perfect. The exhaust wire and casing had been accidentally pinched and did not work freely. These were both replaced, care being taken that the lengths of both were exactly the same as the old ones. E.M.

[In Part II. the repainting of the motor cycle and thorough overhauling of the sidecar body and upholstery will be dealt with.—ED.]

# A NEW AMERICAN FLAT TWIN.

Many New Ideas embodied in a Somewhat Unconventional Design.

**T**HE latest flat twin to make its *début* in the States is the 354 c.c. Paramount, produced by the Paramount Motor Co., a firm hitherto associated with the production of automatic screwing machines and other fine gauge work of that kind.

The Paramount motor cycle possesses many novel and excellent features, and the chief claims of the manufacturers are centred around its vibrationless and noiseless running. The layout of the engine is somewhat peculiar. Our photograph shows the fly-wheel side of the machine, and on the opposite side is the transmission.

## A Unique Valve Mechanism.

On the crankshaft is mounted a phosphor-bronze skew pinion which engages with a pinion giving a 6 to 1 ratio. This second pinion is mounted on the camshaft, and the valves are operated by means of three cams running at one-sixth engine speed. This patented mechanism is claimed to be absolutely silent, and if this be carried out in fact the system is certainly worthy of the attention of British manufacturers. The large 6 to 1 pinion is coupled direct to the clutch, which is of the multiple-disc variety containing ten gin. discs. Its very considerable friction surface permits an unusually smooth action, while indefinite slip can be permitted without heat owing to the light pressure on the plates. It will be seen that, by means of this design, an absolute minimum of driving pinions are employed, and thus friction and noise are proportionately reduced. The two pinions already referred to are the only two in the entire unit, and answer the purpose of driving the valve mechanism in addition to transmitting the power. The magneto is contained in the flywheel, and here, too, the use of gearing is eliminated. The patented magneto is claimed to be absolutely foolproof and mudproof, and, while it requires no adjusting whatever, it is stated to produce a very hot spark, even at low engine speed.

## Transmission and Frame Design.

The driving pinion is mounted on a large double row annular ball bearing, and the highly efficient clutch answers the purpose of gear box, as in the case

of the 7 h.p. sporting model Indian. The clutch is controlled by means of a long hand lever, which can be notched in any position to give the desirable amount of slip.

The carburetter also is uncommon in motor cycle practice, in that no springs are employed anywhere in its mechanism. All adjustments are external, and it is claimed to give the engine an exceptionally good tick over on the pilot jet.

The frame, it will be noted, is of the cradle or loop variety. The curved frame member from the

steering head to the engine bracket is not suggestive of strength, but in all other respects the frame design appears to be passable. This curved member is of seamless steel, and its bottom extremity is let into a drop forged T. At the back end of the cradle is a second drop forged T, from which straight tension stays extend to the rear wheel spindle.

The drive is direct from the clutch by single chain, and the

gear ratio on positive drive is 6 to 1.

The front forks, it will be noticed, are somewhat on P. and M. lines, minus the spring sheaths. The "gasolene" tank is pressed out of a solid piece of deep drawn steel and is absolutely seamless. Twenty-six inch wheels are employed, and the kick starter is entirely enclosed. Only one brake is fitted, this being an internal expansion brake in the rear wheel.

## Following British Practice.

It would appear that this machine is an outcome of British practice. The flat twin of approximately the same c.c. has rendered such excellent service in France that the Americans frankly admit that a huge market awaits this type of mount in the States. We have in the Paramount what is practically equivalent to a Douglas, with the exception that a highly efficient clutch takes the place of the gear box. It is claimed that, as a solo mount, the Paramount is equal to any road conditions, and its h.p. is set down by the makers at 4-5 h.p. The 6 to 1 camshaft is certainly an interesting feature, and the great reduction in pinions and engine parts opens up a new line of enquiry. We look forward also to the adoption of the flywheel magneto over here.

The Paramount flat twin, of 354 c.c.—a recent American production. The makers designate it as a 4-5 h.p.

## HANDLE-BARS.

"THANK goodness," sighed the D.R., "that manufacturers have at last brought a little common sense to bear in the matter of handle-bars."

The elderly member of the trade regarded him narrowly. "It's not a question for the manufacturers at all," quoth he. "At the moment we are catering for the young blood—the D.R.—and we have pampered for his popular fancy, much against our own convictions."

"Not all D.R.'s are 'young bloods,'" retorted the Discharged Soldier, promptly. "The majority are experienced men, who are seriously in earnest. Nor is it a matter of popular fancy, but rather one of dire necessity. The semi-T.T. bar has been chosen because it gives proper control—not because it is 'knuttish.'"

"Quite true," agreed the Novice, "but at the same time you must admit that the D.R. is a young man, and generally a hard rider. Naturally he prefers the sporting bar; but that in no way proves that the touring type is wrong or that other people do not want it."

## Design of Necks.

"Moreover," pursued the Manufacturer, "the present type of wide bar was fashionable before the war. I myself was caught by the invasion, and invested in a pair, only to discover that they made my neck ache."

"That was because the design of your neck was wrong—not the bars," the D.R. told him, bluntly.

"If one has a giraffe's neck and a serpent's body," sneered back the Manufacturer, "then doubtless one could ride all day in comfort with that type of bar."

A momentary silence followed. It was noticeable of late that the friendship between the Manufacturer and the D.R. was becoming somewhat strained. Presently, to even things up, the Journalist took the Discharged Soldier's part. "I have used semi-T.T. bars for years with comfort," he observed, "and therefore I must have a giraffe's neck and a serpent's body. I, moreover, am not a young blood; in fact, I am rather getting on in years; yet if I had any choice in the matter I should never use touring bars."

The Novice turned to the D.R. with the air of having suddenly remembered something. "Look here," he said, "quite recently you rode from London to Coventry in pretty fast time on an Indian fitted with extreme touring bars, and on arriving here you told me that the position was thoroughly comfortable. Remember that?"

The D.R. fumbled with his watchguard. "Sure I do," he agreed. "I have ridden scores of machines with touring bars,

which I admit were comfortable, but that does not alter my opinion as to the design being wrong. I say that the upward-sweeping bar is, like the average mud-guard and front wheel brake, an undesirable relic of pedal cycle days which would never have occurred if the motor cycle had possessed no predecessor."

"But why is the touring bar wrong, I should like to know?" demanded the Novice.

## The D.R. Bored.

The D.R. looked bored. He turned to the Journalist. "Oh, tell him!" he pleaded.

"Well," the Journalist began, "in my opinion it is wrong, because, in the motor cycle, we have three important factors to contend with which in the pedal cycle do not enter into the reckoning—namely, speed and weight (which demand maximum control), wind resistance, and the constant forward pull of the machine. To counterbalance the latter the rider should lean very slightly forward, otherwise the whole of the strain falls at the bottom of his back. By leaning slightly forward he lessens wind resistance, and thus further relieves his muscles. Moreover, if the design of the bars is such that the forward pull is taken through straight arms with the body in a comfortable and natural position, it is obvious that the constant forward pull is less tiring to the biceps of the arms than if it be taken through bent elbows."

"Hear, hear!" muttered the D.R. "I couldn't have put it more clearly myself."

But the Manufacturer was becoming restive. "I don't think your arguments hold water," he stated. "In the pedal cycle there was a *real* reason for using dropped bars, because they gave you better control of the pedals, but on a motor cycle, provided the steering and balance are perfect, it should not be necessary to resort to leaning forward and stooping. My present mount positively steers itself. I could ride hands off along a chalked line at anything between 10 and 40 m.p.h. Why then should I resort to a congested and unnatural position?"

"Just so," agreed the Novice; "if the design of a machine is so rotten that one has to resort to racing bars for touring purposes, then the best thing for the designer to do is to try something fresh. Personally I think that the best and most natural position is the one you would assume when seated naturally on the saddle—that is, with the bars comfortable near to you."

"What is your most natural position?" queried the Journalist. "Take yourself—take a savage seated by his fire. He sits with his body inclined slightly forward, his elbows on his knees, so as to relieve his spine."

"Of course he does," the D.R. added. "An upright position is not the most natural, because all the weight is on the back. Moreover, you cannot say that your most restful position when the machine is stationary is necessarily the most restful when the machine is going, because, with the machine stationary, neither wind resistance nor acceleration is exerting its influence."

"Do you know," queried the Manufacturer, "that in France to-day the D.R.'s bend their semi-T.T. bars by hand to suit their requirements? Half of them cuss the extreme bars now sent out, and before they ride a new machine they redesign the bars to a more moderate shape."

"Individual tastes naturally exist," observed the Journalist. "But do you consider that the distribution of weight in the Scott motor cycle is good, and that the steering is as near perfect as on any present-day motor cycle?"

"I do," stated the Manufacturer. "You do? Then let me tell you this as illustrating the point of control. Recently I possessed a Scott, fast, though not freakish. I had the ordinary touring bars, which were so comfortable that I threw discretion to the wind, and stuck to them. The result was that three times in about three weeks I came an awful purler on corners—my front wheel simply shooting straight from under me in a dry skid ere I had any notion that I was taking risks. My landlady implored me to sell the machine—(cheers from the D.R.)—but I said 'No! I will obtain a pair of T.T. bars.' I got them, and after that, not only was my control more perfect, but I seemed better able to estimate the speeds at which I could safely negotiate bends. I had no more spills."

## The D.R. Tries a Flat Twin.

"Let me substantiate that," said the D.R. "Recently I went to Nottingham, and Mr. Brough lent me one of his flat twins to make a journey of fifty miles. The machine was fitted with ordinary touring bars, and on my return I told Mr. Brough that, owing to its speed, it was positively dangerous with bars of that type. He agreed, but said purchasers desired them."

"Returning to Scotts," argued the Manufacturer. "Let me tell you that Tim Wood, who should know something

**The Critics.**

about that make, always rides ordinary touring bars because he prefers them, and so did that other man they used to have—Stewart, the trick rider. Those men ought to know.”

“And what about the recent American speed records which have astounded the motor cycle world?” put in the Novice. “You yourselves admitted, when we discussed big twins, that these records were as much a test of human endurance as of machines. Well, let me tell you that the creators of these records rode what you would call extreme touring bars. If the layout of the human anatomy is such as to demand T.T. bars, how then is it that these men have endured wind resistance and speed which beat all previous records in history? Could they have done it if their spines were subjected to undue strain? Could they have done it if their position and their control were wrong? Assuredly not! Therefore you two are talking through your hats.”

The Journalist observed that he had never possessed a hat worth talking through since the Novice came to visit

him. Hat stands, he remarked, were considered by some people as an open exchange.

**Sticking to the Point.**

The D.R. observed that the landlady was evidently out of coppers, and that the gas was going down. “Why don’t you put Indian or Henderson lighting installations to an endurance test?” he asked the Journalist.

“You two chaps are trying to shin out of it,” observed the Manufacturer, bluntly. “We are waiting for a straightforward reply to our last argument.”

“My reply is this,” said the Journalist, “that only one thing can decide this argument—that is, personal taste. It is a subject which is even open to debate, which proves definitely that it is a matter of personal taste. Every rider must decide for himself which type best suits his requirements. The staid individual should not condemn the T.T. type because he considers it knuttish, neither should the youthful enthusiast condemn the touring type because he regards it as ‘old gentlemanly.’ Practical men of the road should be above such petty bias. I like the T.T.

type; you like the touring type. Very well then; let manufacturers do as they have done in the past, and supply both types to order.”

Everyone agreed that this was sensible. “But,” said the D.R., “on the Indian we have an adjustable bar, which gives one a wide range of movement to suit one’s stature. I think British makers might advantageously follow this lead. After all, the most comfortable position for the bar depends very largely on the position of the footrests. In my opinion, both should be adjustable within a reasonable range to suit the length of limb of the rider. Those who agree kindly signify in the usual —”

Four hands went up, while the Journalist’s dog, having spent the last five minutes in a futile endeavour to catch a bluebottle, finally, at this very crisis, downed him and ate him. But, in truth, the bluebottle was still at large, while the worthy canine, gazing in adoration into his master’s eyes, wist not that what he had eaten with the relish of a conqueror was a well-baked sultana, dropped from a war-time scone that tea time.

## A New Lighting Dynamo from the States.

The Latest Splitdorf Dynamo is Easily Attached to any Make of Motor Cycle.

A VERY interesting dynamo lighting set which should meet a popular demand, since its simplicity renders it readily adaptable to any make of machine, has been produced in the States by the makers of the well-known Splitdorf and Dixie magnetos, and has recently undergone a series of exhaustive tests by which its efficiency is proved. The new Splitdorf dynamo is a small and compact unit of remarkably high output, and it can be attached to the frame in any position which permits the drive from the engine-shaft. This drive is by spring belt, the generator running at one and threequarter times engine speed. The output can be varied to suit demands, but for ordinary use it is used in conjunction with a 6 volt 15 ampere-hour storage battery.

**Wiring and Control.**

One attractive feature of this model, which is known as the DU-1, is its entire absence of outside fittings, and, except for the simple ampere meter, the unit is self-contained. An automatic control regulates the current between the generator and the storage battery, discon-

The new Splitdorf dynamo. Note the clean exterior and the single wire. The second connection is earthed.

necting the battery at low speeds, and connecting up again when the dynamo voltage rises above the battery voltage. This control, we are informed, is not electrical, and, therefore, we conclude

that it is operated on the governor principle, the makers claiming that its working cannot be hindered by road shock.

**A Simple System.**

The wiring is simple, the “earth” system being employed—the single wire passing direct from the generator to the ammeter placed on the top bar, then on to the battery. The ammeter can be dispensed with if desired, but the makers point out its usefulness in indicating the exact condition of the battery, which otherwise must be left to guesswork. The regulating device is so arranged that it can be set to give an increased output for the winter months when the system is in constant use, so that overcharging or undercharging can be avoided by means of a simple adjustment. It is noteworthy that the Splitdorf Co. has diverted from popular American practice in producing a system in which the lighting and ignition are entirely separate, so that failure on the part of one does not involve the other; and if this readily adaptable unit is to be marketed at a popular figure, there is no doubt that it will be in demand.

## Chain Speed and American Methods.

IT is not always realised that a low-speed chain is subjected to greater tension than a high speed, and that it is not tension that decides its life. In an all-chain drive, the chain from the engine to the countershaft is subjected to less tension than the main drive, yet it is generally the first to go on account of the higher speed at which it runs. An enclosed pinion drive from the engine to the crankshaft is mechanically better than a chain, but, unless skilfully made and

designed, it would probably prove a good deal noisier. Fibre pinions might go a long way towards eliminating noise, and in this we can take a hint or two from America.

Dwelling still further upon the trend of American affairs, the rear car, though it may appeal to us as ugly and cumbersome, offers certain advantages for trade purposes. In the first place, the wheels of the car entirely support the load it carries, and an overload does not

impose any extra strains on the motor cycle frame. The motor cycle obtains a straight pull, and there is no question of alignment. One becomes used to the appearance of the beast, and we understand that it is capable of carrying enormously heavy loads without detracting very noticeably from the speed of the machine. As a trade attachment it undoubtedly has its virtues; yet another among which is the ease with which it can be attached and detached.

## MILITARY NOTES.

### Comment on Despatch Riders—their Dangers and their Work.

#### G.S.W.A. CAMPAIGN.

**R. OTTLEY** (Lt.), who was in the G.S.W.A. campaign, writes us concerning the photograph published on this page: "I have unfortunately forgotten the actual name of the place in G.S.W.A. where my snap was taken. While we were attached to the Inf. Brigade, under Gen. Bevis, myself and six despatch riders were sent ahead in advance of our squadron as scouts when we came across the bridge shown in the photograph, which had been blown up by the Germans only a few minutes before our arrival."

□ □ □

#### D.R.'s AND THE DANGER ZONE.

**L. T. D. PARBURY**, of the A.S.C., writes as follows, taking exception to statements as to the number of motor cycles which have been damaged by shell fire: "Referring to *The Motor Cycle* of June 14th, 1917, do not you think it is rather unfair to alarm people at home by such exaggeration as to the dangers to which our motor cyclists are exposed? Being connected with a motor cycle casualty clearing station, I can assure you that not more than 1% of damaged motor cycles have suffered from shell shock. It may be a very sensational statement that most machines have been shelled, but it is not true. The five or six examples produced by the corporal-artificer would be nearer the truth."

#### A YOUNG D.R.

"I WAS very interested in the paragraph in *The Motor Cycle* respecting the youngest despatch rider. Although I cannot claim to have been a despatch rider, I can claim to have ridden a Triumph within the range of machine guns as well as other guns, round that much-heard-of salient of Ypres, at the age of 15½ years. I joined the R.A.M.C. in May, 1915, at the age of 15 years 21 days, and went to France on September 8th of the same year. I eventually arrived at a Field Ambulance attached to the Guards Division, where I remained till July 24th, 1916. I may say that the ride landed me in hospital for three days, owing to running into a shell hole and getting thrown out and injuring my shoulder slightly. Wishing you success to the 'Blue 'Un,' **ROBERT JUYOMS.**"

□ □ □

#### SARCASTIC.

**CPL. A. SIMPKINS** writes us in a sarcastic vein anent the articles on "D.R.'s and their Work." It is natural that views on such a wide subject should be diverse, and we publish this candid criticism as giving another point of view on the work of despatch riders.

"After reading the second article on 'D.R.'s and their Work,' by 'D.R.,"

may I ask what D.R. stands for? Surely not despatch rider. If it is supposed to be a descriptive article of a D.R.'s life, probably it was in some other war—not this. When I read of spy chasing and submarine hunting it makes me think they must have a war on in Blackpool.

"I have had over two years' experience in France as a Divisional D.R., but I cannot recognise my job. And having photographs taken—My! I would not care to be the man caught with a camera anywhere within five miles of the line: sudden death or lesser punishment would be his portion.

"It is now clear why the corduroy plank roads are made, and why the huge shell holes filled with boulders—so that the D.R. may have his photograph taken; but why (do the shells scream so much and bite chunks out of the road? Not for the same reason surely.

"If the article refers to this war it is as true to life as the Irish professor's description of a crab: 'A small red fish which walks sideways.'"

□ □ □

#### NEW TANK COMMANDER.

**THE Duke of Westminster**, who did so much good work with the Armoured Car Section in Egypt, has now returned to England, and has been appointed second in command of one of the Tank battalions.

Advance scouts in German South-West Africa crossing a bridge which had been blown up by the retreating Germans only a few minutes previous to the photograph being taken.

# ROAD EXPERIENCE WITH COAL GAS.

The Results of some Practical Experiments Arising from the Petrol Scarcity.

**D**RIVING petrol motors with coal gas is nothing new. The writer as far back as 1901 successfully ran an engine with it. The cause that led up to the experiment was the fracturing of a petrol supply pipe on a test bench. Motors in those days would not allow of a glass of water standing on them while running under test at 4,000 r.p.m., hence the fracturing of the petrol pipe.

The engine in question was turned out by an amateur from particulars given in a journal on "How to Make a Motor." It certainly ran: it also walked the test bench about the shop. The experiment with coal gas was fairly successful: trouble was caused by water in the pipes, which gave an unequal pressure, but ultimately a fabric bag was rigged up, the supply drawn from this, and smooth running as far as the engine would allow was obtained.

For some time now many works have adopted coal gas for test branch work, so little more was required in the fitting up of a motor cycle having a suitable chassis.

Messrs. Campion, of Nottingham, having received urgent orders for aeroplane fittings that required oxygen welding, were frequently tied up owing to the non-delivery of the oxygen cylinders by the railway company. No local supply being available, some quicker and surer way of getting delivery was necessary. Petrol being out of the question, recourse was had to coal gas, which, it may be at once explained, has given highly satisfactory results, and for those people who do town running or short distance work the question of propulsive power is solved. Experiments are being carried out which will still further enhance the value of coal gas, but particulars cannot be given at this stage. The running of the motor cycle and sidecar fitted with gas container has caused a mild sensation locally. The Campion motor cycle is fitted with an engine of large capacity, being an 8 h.p. twin J.A.P., having cylinder measurements of 85.5 x 85 mm.

Owing to the heavy weight to be carried and the condition of the roads, and having at one part a stiff hill with a 1 in 7 gradient, the question of a larger mileage with a 4 h.p. engine was ignored. A specially strong sidecar chassis was fitted capable of carrying oxygen cylinders weighing well over 3 cwt. The journey out and home to the Brush Works,

Loughborough, is thirty miles. For the return journey a recharge of gas was taken up at Messrs. Campions' local depot at Loughborough. The return journey, being somewhat easier running, was taken on a top gear of 4½ to 1.

The capacity of the envelope, which is well raised above the chassis, is fifty cubic feet. At the Nottingham power rate of 2s. per 1,000 feet of gas, this works out at a little more than a rd. per charge of fifteen miles, and it is important to note that this is made with an engine of large capacity with a fairly large jet, pulling a heavy load over indifferent roads having stiff gradients. The envelope, which is tested up to a pressure of 12in. of water column, can be filled without any mechanical assistance, a small length of rubber pipe being all that is necessary, but

to facilitate filling it is better to unscrew the burner. The time of filling varies with the diameter of the supply pipe; a 1in. pipe as usually fitted in a garage would fill up in about thirteen minutes. The matter of fixing up such a supply in all the East and Midland County depots of Messrs. Campions is being considered. A very important point is that no over-charging of the envelope can take place. No matter how long the envelope may remain in connection, the pressure from the

The 8 h.p. Campion used in carrying out the tests.

main varies from 3in. to 6in. water column, dropping down as low as 1½in. on the occasion of a Zeppelin raid alarm. The charging is arranged from the bottom of the envelope, the gas immediately rising in the bag to its highest point: an interesting fact is that no escape occurs when fully inflated, even with the bottom tap left open. Owing to the gas being well above the point of supply, no back pressure occurs, as when fully charged, and before any running of the engine has taken place, if the machine is taken in the sunshine, there is an immediate raising of the pressure, the fabric bulging out between the supporting cord in the same manner that a scent spray bulb will distend under pressure.

As in a balloon, normal pressure is restored by opening the control tap at the bottom of the envelope, which allows excess pressure to escape, and it is important to remember that the escaping gas being unadulterated is *not* explosive. After standing fully charged for a period of three to four days there is

### Road Experience with Coal Gas.—

a loss of not more than one half to one cubic foot of gas. When running a change over from coal gas—which, by the way, requires all possible air—to petrol the change can be made in the easiest possible manner without stopping. The gas in the bag is drawn off by engine suction to the last fraction, so much so that the envelope collapses and the sides are held together

by atmospheric pressure. After a short time one gets quite accustomed to the unconventional fitting on the sidecar, which is by no means clumsy to drive. Demonstrations have been given before a cinema operator, and when the films are released motor cyclists will see with what ease figure 8's and circles are taken on a narrow road. The only alteration required to the machine is one that will cost but a few coppers.

## Further Records on the American Speedways.

### NEW U.S.A. SPEEDS ACCOMPLISHED.

As will have been seen from these pages, there has been a good deal of record-hunting going on lately in the United States, where there appears to be petrol enough and to spare, and, notwithstanding the demands of the U.S. Navy and Army, motoring is still able to progress, and there is considerable activity in the motor cycling world.

At Cincinnati, on August 15th, Erwin G. Baker, who has earned for himself the pseudonym "Cannonball," again established motor cycle records on his Powerplus Indian on the Speedway in that City, thus duplicating his performance on June 28th on the same track.

Baker set up a new twenty-four hour record of 1,534½ miles, a twelve-hour record of 821½ miles, while he covered 500 miles in 6h. 14m. 15s. Both the 500 and 1,000 mile times are world's records.

Baker's record of 1,534½ miles exceeds that formerly held by Parkhurst (Harley-Davidson) by 81¾ miles. His time for the 1,000 miles was 54m. 13s. better than that of Parkhurst, and for the 500 miles 36m. less. Baker also eclipsed his own record of 702 miles in 12h.

Erwin G. Baker, known in America as "Cannonball," and his Powerplus Indian, on which he accomplished the records.

The average speed for the entire twenty-four hours was nearly 64 m.p.h. as against 60½ m.p.h. average on the occasion of his former record. This is certainly a wonderful average. The time occupied by Baker when he was not riding was 2h. 23m., so that his average running speed was 70.9 m.p.h., which is 8 m.p.h. faster than his previous record.

While Baker was gaining triumph after triumph, Teddy Carroll, on a Powerplus Indian sidecar combination, taken from stock, was

establishing new times for the twenty-four hours and intermediate distances. In the twenty-four hours his distance was 1,275½ miles, improving upon the former figure made by Walker by 117¼ miles. Carroll covered 500 miles in 8h. 56m., and 1,000 miles in 18h. 48m., while in twelve hours he had travelled 661½ miles, setting up new world's records. For the

500 miles he was 51m. 42s. better than Walker. He covered the 1,000 miles in 1h. 34m. 46s. less time than the previous record holder, and averaged over 53 m.p.h. for the entire twenty-four hours.

The many extraordinary records that have recently been put up in the States have none of them for long remained unbeaten, and it is conceivable that the above remarkable times will, in the near future, be eclipsed.

THE FIRST CLASS OF PUPILS AT THE HARLEY-DAVIDSON SCHOOL OF INSTRUCTION.

In order to familiarise army officers with the construction and mechanism of the motor cycle, the Harley-Davidson Service Department has been made a school of instruction. This primary tuition will be succeeded by lessons on driving and repairs on the road

## MEMORIES OF THE OLDEN DAYS.

### SOME REMINISCENCES OF A PIONEER MOTOR CYCLIST.

“Où sont les neiges d'antan?” “Where are the snows of yester-year?” How can we ever recapture that feeling of “the first time,” the first hearing of “Tristan und Isolde,” the anticipation in cutting the leaves of a great book, the first soar into the third dimension on a modern aeroplane, and—our first run on a motor cycle!

1904 seems a long while ago now; peace had just come, and the writer was one small unit in a big public school. Every week we eagerly devoured *The Motor Cycle*, and about the time of the National Show our pockets would bulge with catalogues. These were the days of Edge and Jarrott, George Barnes and Hooydonk, and many others. Save perhaps Harry Martin and Tessier, where are they all now?

A few years before I had seen my first self-propelled vehicle—a De Dion tricycle, with the  $2\frac{3}{4}$  h.p. engine (high power for those times) mounted over the back axle. It chugged solemnly round Battersea Park and disappeared, leaving a small boy whose only wish in life was to possess one like it!

The early “Bat” motor cycles, with  $2\frac{3}{4}$  h.p. De Dion and M.M.C. engines, came in later. At one time this capable machine, with its quaint handle-bars and round brass tank, held every record between one and fifty miles.

Who that heard it will forget the queer hollow note of its automatic inlet? The makers dispensed with pedals, and there was a great discussion at the time as to the advisability of this, for how was one to get home? (That was a paramount question in the days of accumulator ignition. I shall never forget seeing the unfortunate owner of a hefty twin “Rex” pedalling his several hundredweight of iron with the belt off, his feet spinning round to a fifty gear with tiny cranks. It was a labour of Hercules.) But the “Bat” came and conquered, and we never went back to pedals.

#### Hill-climbs and Racing.

One of the great events of the year at that time was the Westerham hill-climb. This is a declivity that even nowadays compels respect; the long rise from the village before the actual hill is reached calls for an engine with stamina. The Chase-Jap match, which Chase won by a narrow margin, is still remembered in the village.

By this time the sport was in full swing, and Harry Martin on the old high-built “Excelsior” (inclined M.M.C. engine, I think it was) hotly contested the honours with Hooydonk, on the Minerva-engined

“Phoenix.” I can see them now, the old crowd, roaring round the easy bends of the Crystal Palace track, craning feverishly over their tanks, squatted on luggage carriers (the racing man at least realised the danger and uselessness of the old high position).

#### Forecars to 3 h.p. Machines.

What a far cry from those days to my imperturbable little Douglas, and how I could have swept the board with it if I had only had it then!

About this time the makers turned to passenger-carrying vehicles. Forecars were bolted on to 3 h.p. machines. Speed gears were not, and often we walked, pushing several hundred pounds of sullen and over-heated machine. Heavy three-wheelers with labyrinthine machinery came into vogue, and died a natural death.

Racing motor cycles had to come within a weight limit, 110 lb. I think it was, and we were at fearsome shifts to crowd 12 h.p. into these limitations. Somehow we did it, with light gauge frames, cycle tyres, saddles cut into patterns, and pulleys drilled till they were mere cobwebs. It was a risky game, and many a frame lug was found cracked after a speed burst.

#### 14 h.p. Peugeot.

I well remember the famous Brighton meeting, when Cissac came over with his 14 h.p. Peugeot wonders, geared about  $1\frac{1}{2}$  to 1, which according to popular rumour destroyed one back wheel, tyre and all, each time they were used! Barnes put up a very plucky fight against the Continental crack on a little 5 h.p. Deckert single-cylinder, with ports drilled below the piston stroke as was our practice then (and the oil they used!) At that meeting Rolls and Moore-Brabazon drove, and there appeared the 200 h.p. “Dufaux” car, all engine, with a cane seat lashed on somehow—a fearsome beast, which was badly beaten by several more practicable monsters of considerably lesser power.

But Rolls is dead, and of all that merry company of sportsmen, how many shall we meet when the war is over? Never mind, it was there they learned to “play the game,” and our Teuton friends can bear witness that they play it well.

R.H.B.

#### NOTICE.

The Editor disclaims all legal responsibility in any way for loss of copy in the form of manuscript, drawings, or photographs submitted to him. Rejected matter will only be returned provided a stamped addressed envelope is enclosed for the purpose.

Special  
Features

## SUMMER TIME.

Sept.	6th.	...	...	8.5	p.m.
"	8th.	...	...	8.1	"
"	10th.	...	...	7.56	"
"	12th.	...	...	7.52	"

## Captured German Motor Cyclist Airman.

Von Shultz and Flink, two interned enemy airmen—the former said to be a motor cyclist—who escaped from Maidenhead, and were captured by a police dog in a Kent lane leading to Cudham, are said to have planned to escape on an aeroplane. It is more probable they hoped to hold up a sidecar near a certain Kent common, a favourite rendezvous for motor cycle short runs.

## A Very Raw Recruit.

For some time past we have noticed one who is obviously a beginner riding in the residential districts of Coventry apparently in fear and trembling during his evening leisure. He rides a very neat little Douglas machine; and should he chance upon these lines, we wish to inform him that during the last fortnight or more his engine has been firing in one cylinder only.

## Second-hand Prices in France.

Our French correspondent writes us: "I read in *The Motor Cycle* the suggestion that Red Cross war worn motor cycles might be sold here. If anything in this line could be done it would gladden the hearts of most of us. High prices! A Rudge, second-hand (already spoken of to you), T.T., I.O.M. model with few alterations, brought to its lucky owner 2,400 francs! Taking £1 as equivalent to 25frs., this amounts to £96! I regret I sold my Rudge at the beginning of the war for £40."

## Auxiliary Patrol.

There are still vacancies for men of good character as chief motor mechanics. Candidates must be over twenty-two and under forty-five years of age. Pay 5s. 6d. per diem, and allowance of 3s. per diem when not serving on shore or in depot ships.

There are vacancies also for motor mechanics. Candidates must possess a good knowledge of four-cylinder petrol engines, and have had two years' workshop experience. Candidates must be over eighteen and under forty-five years of age. Pay 2s. 6d. per diem, and allowance of 3s. per diem when not serving on shore or in depot ships.

Apply by letter to: Engineer Officer, Auxiliary Patrol Office, Admiralty, London, S.W.1.

## Motor Cyclists Wanted.

The British Ambulance Committee require immediately several motor cyclists for service on the French front. They must have had at least three years' experience in sidecar driving, should have good eyesight, as they would have to drive very often by night without lamps, and should not be over thirty-five years of age. Preference will be given to discharged soldiers. Full particulars and qualifications should be sent to the British Ambulance Committee, 23a, Bruton Street, Berkeley Square, London, W.1.

## An Irish Journalist's Success.

The Lord of the Admiralty has appointed Mr. J. C. Percy, of Dublin, well known in journalistic and motoring circles, to be Honorary Lieutenant of the Royal Naval Volunteer Reserve.

This honour has been conferred in recognition of Lieut. Percy's conspicuous services during the past two years as honorary organiser of Naval recruiting in Ireland. There are few towns or villages in the Emerald Isle which he has not visited in order to tell the story of the Navy's needs and deeds.

## Petrol Prices Again Raised.

Petrol prices were advanced by 8½d. a gallon on Monday last. This large increase came as a surprise to motor cyclists, who now have to pay over 4s. per gallon for their petrol.

## A Warning.

While three Manchester boys were hammering a motor spirit cask, which they believed to be empty, it exploded. Two of the boys were instantly killed and the third was injured.

## Early Spring Frame.

The early spring frame model we illustrated last week, and which a correspondent submitted as an experimental spring frame Bat distinct from the ordinary spring frame model, now transpires to be a spring frame Rip, the design of which is certainly reminiscent of the early Bat models.

Old-timers will recall the first appearance of the spring frame Bat and the interest it created, making its *début* even before spring forks were recognised as attainable; while the fact that the system of springing first employed still lives signifies the soundness of the principle.

A new American lightweight, known as the Evans power cycle. It has recently been placed on the market by the Cyclemotor Corporation, New York. The complete outfit weighs only 65 lb., and can be handled like an ordinary bicycle.

### The National Relief Funds.

At the week-end the principal war relief funds stood 'as follow :

The National Relief Fund (distributed £3,641,622) .. ..	£6,226,647	0	0
British Red Cross Fund .. ..	7,256,310	9	7
Tobacco Fund .. ..	136,223	18	10

### Petrol and Race Meetings.

At the Birmingham Police Court recently six men were summoned for allowing motor spirit to be used, and for using motor spirit, for the purpose of proceeding to a race meeting. The magistrates agreed that the offence was a nominal one. Three of the defendants were fined 20s. and the driver 10s.

### "Motor Cycles and How to Manage Them."

A new and fully revised edition (the eighteenth) of "Motor Cycles and How to Manage Them" has just been published by Iliffe and Sons Ltd., 20, Tudor Street, London, E.C.4 (price 1s. 6d. net, by post 1s. 10d.)

Although during the war the progress of motor cycle design has by no means been at a standstill, developments have been mainly along accepted lines, with the aim of securing increased reliability and accessibility, greater economy, improved transmission, lubrication, and so on. Consequently no very striking alterations were necessitated in the work of revision. On the other hand, many detail improvements and alterations have taken place since the previous edition was printed, and these have been duly noted in their proper sequence throughout the book. The chapter on two-stroke engines,

for instance, has been amended, as has also the chapter on lubrication; while the section devoted to high-tension magnetto ignition has been largely rewritten, and now includes particulars and illustrations of all the latest British and American machines.

### Well-known Competition Rider Married.

Sec.-Lt. Alan B. Hill, R.F.C., late of *The Motor Cycle* editorial staff, was married on September 1st to Miss D. Nicholls at All Saints Church, High Wycombe. Mr. Hill was well known in the competition world in pre-war days as a rider of Indian and Rudge motor cycles, and he also competed successfully in several events with a Humberette cycle car. Lt. Hill has seen service in France as an ambulance driver, after which he was invalided home, but obtained a commission in the R.F.C. early this year.

### The Joy of the Open Road.

We witnessed a pretty sight the other day in the neighbourhood of Leamington—a baby two-stroke gamely struggling along with a great disabled twin in tow.

Whether the two riders were enjoying the procession as much as the onlookers is open to question. Certainly those who recognised the two riders thoroughly enjoyed the sight, especially on the inclines, when both men lustily paddled the machines until they appeared to be on the verge of apoplexy. It was a sight worthy of the gods!

### Brooklands Models.

Norton Motors, Ltd., draw our attention to the fact that very often machines are sold, possibly inadvertently, as Brooklands Specials, which do not hold the official Brooklands certificates.

The owners of Norton machines, which were sold to them as Brooklands models, can obtain confirmation or otherwise of this fact by submitting the engine number and lettering to the makers.

### Average Prices.

We give below the prices of second-hand machines offered for sale in the last issue of *The Motor Cycle*, and in the adjoining column the average prices based upon the latest figures available. Thus the general trend of the market is visible at a glance, though in the first column many blanks must inevitably occur.

### The Motor Trade To-day.

*The Birmingham Post*, reviewing the motor trade for the week, says that the motor cycle industry is at a standstill, except in those factories which have military contracts on hand. If the materials for manufacture were obtainable, the failure of a petrol supply would be fatal to this branch of trade for the time being.

The interruption of a large contract placed some time ago on account of Russia has thrown a certain number of machines on the market. They are built very high, are heavy, and altogether not quite the type which ordinarily finds favour with British riders, but they will, no doubt, be put into service when the necessary motive power is procurable.

DESPATCH  
RIDERS.

Ladies are now acting as despatch carriers and sidecar drivers for the A.I.D., their attire being service uniform of khaki. The combination is a 5-6 h.p. Clyno.

# A Thousand Miles in Nine Days.

A  
Run to the Southern  
Counties on a 3½ h.p.  
Sidecar using Heavy  
Fuel.

THE following article will, I hope, interest many motor cyclists, proving what can be accomplished by a first-class 3½ h.p. machine using 71% white spirit and 29% petrol.

First of all, let me give an account of the machine. One always likes when reading a description of a tour to know in the first instance something about the machine, as then one can better appreciate the experience of the author as one goes along with him.

The combination that served us so well was a 3½ h.p. Sunbeam, fitted with Sunbeam leg-guards. It was purchased in July, 1915, and since that date has been out in all weathers. rain or snow, and runs as well now as the first week of purchase. The only necessary overhaul, apart from clearing carbon from the cylinder, was that of the gear box.

Previous to this machine I rode a 3½ h.p. Triumph, with N.S.U. two-speed gear and Millford Empress sidecar. On taking over the Sunbeam there were two matters that disappointed me. The first was the constant changing from top gear to second on short hills, and on long hills near Bradford down to low gear. The second point I disliked was the rigid footboards. As the roads are at the present time, they were anything but comfortable, so I procured four spiral springs similar to those used on the James, and fixed these under the footboards, and thus effected a wonderful improvement. With regard to the gear, I wrote to the makers and asked if they would supply me with a 14-tooth sprocket to make the top gear 6 to 1 instead of the 16-tooth sprocket which gives a top gear of 5¼ to 1. They informed me they could not supply one, and that all their advertised performances were done on standard gears. However, at a cost of £1 5s. 6d., I got one made in Bradford. If it had cost double it would have been worth it. I can now run along up hill and down dale on top gear. On Pool Bank, near Otley, I ran from one-third to halfway up on top, and then sailed up easily on middle gear and throttle half open, whereas I formerly crawled up the last half on low gear.

Having ten days' holiday, from August 11th to the 20th inclusive, I planned the tour given herewith from the Michelin guide-book, which has proved itself to be invaluable.

## Arranging Spare Fuel and Luggage.

Thursday evening was spent cleaning the cylinder, grinding-in valves, and oiling all working parts. After reassembling, the engine started up at the second kick after a petrol injection. One proof of the beneficial effect of lowering the top gear to 6 to 1 is that, although I had been running on 75% white spirit for some weeks and had done just over 1,000 miles, there was only about the same amount of carbon deposit as I previously had in 500 miles with pure petrol, and, but for the fact of the long tour we were taking, I should not have decarbonised.

I had four gallons of white spirit packed in one-gallon sealed oil tins put in a wooden crate and despatched by goods train to Torquay, and the same quantity to Southampton. On a large luggage grid made of three-ply wood, arranged to fit on the extended chassis of the Sunbeam sidecar, I had four one-gallon tins of petrol and two of blended spirit. These tins were wrapped in felt and each one tied separately, and on the top of this was a large case of luggage, so that we never had so much as a rumble from the tins.

Under the sidecar seat were three sealed tins of mixed spirit, which lasted us until we got to Exeter, when it became necessary to get a tin from the luggage grid. The tank, of course, holds close on two gallons, and in addition we carried a large suit case, which we can just fit inside the sidecar.

Saturday morning, August 11th, at last arrived, and at ten minutes to eight we set off through Wakefield and Barnsley. The roads were bad, and it was deemed advisable, having such a large quantity of unsprung luggage, to run at eighteen miles an hour instead of twenty until we got through to Sheffield. We went out by the Abbeydale Road, through Dore and Totley; here the roads were in fine

## THE ITINERARY.

*FIRST DAY.*—Bradford, Sheffield, Matlock, Belper, Derby (lunch), Burton, Lichfield, Birmingham (meet brother), Bromsgrove, Droitwich, Worcester, Tewkesbury, Gloucester, Stroud. 181 miles.

*SECOND DAY.*—Stroud, Nailsworth, Bath, Wells, Glastonbury, Taunton (lunch), Wellington, Cullompton, Exeter (meet brother), Chudleigh, Newton Abbot, Torquay. 129 miles.

*THIRD DAY.*—Spent around Torquay.

*FOURTH DAY.*—Torquay, Teignmouth, Dawlish, Exeter, Lyme Regis, Bridport, Dorchester, Bere Regis, Poole, Bournemouth, Christchurch, Lyndhurst, Southampton. 138 miles.

*FIFTH and SIXTH DAYS.*—Spent around Southampton.

*SEVENTH DAY.*—Southampton, Winchester, Basingstoke, Wokingham, Bracknell, Windsor, West Drayton. 68 miles.

*EIGHTH DAY.*—West Drayton, Windsor, Twyford, Reading (hospital call), Goring, Wallingford, Abingdon (hospital call), Oxford, Brackley, Towcester, Northampton, Market Harborough. 117 miles.

*NINTH DAY.*—Market Harborough, Leicester, Loughborough, Nottingham, Ollerton, Worksop, Doncaster, Wakefield, Bradford. 122 miles.

**A Thousand Miles Tour in Nine Days.**

condition. After a fine climb up over the moors, from which we got a magnificent view of the surrounding country, we put the gear into neutral and free-wheeled something like two miles down into the village, thence on and through the grounds of Chatsworth House.

This was our first stop, and after watching the graceful deer and admiring the distant view of the mansion, we emptied one of the tins of spirit into the Sunbeam's tank. We then had a fine run through Matlock and Matlock Bath on to Derby, arriving there at 12.15, just fifteen minutes behind our programme time. Leaving there at one prompt, despite a strong head wind, we ran straight through Burton-on-Trent and Lichfield to Birmingham, arriving at 3.5, having done the forty miles in two hours and five minutes without once changing from top gear.

We had arranged to meet my brother at three o'clock. Although living in Birmingham, he was fifteen minutes late, his excuse being, "I thought you would be delayed by the head wind and dust." After a cup of coffee for ourselves and another gallon of spirit for the Sunbeam, we started off at four o'clock. It rained for a few minutes, but soon stopped. From Birmingham until one gets a few miles past the Austin motor works the roads are in a terrible condition, and we had to run very slowly. By the time we got to Bromsgrove things were much better, and from here on through Droitwich, Worcester, Tewkesbury, and Gloucester to Stroud, the travelling was excellent.

**The First Night's Stop.**

At Stroud, it being now 8.30, and having done 181 miles, we decided to stay the night.

On Sunday morning I filled the Sunbeam's tank with another gallon of spirit, and on examining the tyres found a cut in the sidecar cover, through which I could see the inner tube. Needless to say, I soon had the cover off and put a strong canvas patch inside. At 8.30 we started on our journey to Torquay, 129 miles away.

At Nailsworth we had a long climb out of the valley, but this the Sunbeam did well on second gear; then followed a fine run on to Bath, another climb, and a long succession of up and down grades. Just outside Wells the sidecar cover was punctured by a large nail. This delayed us about ten minutes, but we were soon spinning along through Wells, Glastonbury, and Taunton, arriving here fifteen minutes behind the time mapped on our programme. After lunch we replenished the Sunbeam's tank, and set off at 2 p.m. for Exeter, which we reached at 3.45, going through Wellington and Cullompton.

After leaving Exeter we had a long, stiff climb up over Haldon Hill (I think it is called Telegraph Hill).

It was the longest and steepest hill we had come across so far, and for the first time since we left Bradford we had to change down to low gear about threequarters of the way up. Had we been running on pure petrol, I believe the Sunbeam would have taken us straight up on second gear. Onwards we had a magnificent run over the moors, which were purple with heather, through Chudleigh and Newton Abbot to Torquay, arriving at five o'clock.

**Climbing Trow Hill.**

On the Monday we had a walk through the woods down to Anstey's Cove, spent an hour on the water, and then wandered over the Downs and down the cliffs to Oddicombe Beach and Babbacombe. After dinner we brought the Sunbeam out and visited various parts of the town in which my boyhood days were spent.

Leaving Torquay at 9 a.m. on Tuesday, we set off through Teignmouth and Dawlish for Exeter. For the first few miles the hills were very steep, but we accomplished all on second gear.

After leaving Exeter for Lyme Regis, we had to tackle several severe gradients one after the other, but they only served to increase our confidence in the capacity of the Sunbeam to climb anything in reason. After a while, we came to the celebrated Trow Hill, and went up to the last bend without a falter, and then I began to wonder whether we could succeed. The back tyre was a perfectly smooth-treaded Bates, and the

road surface for quite fifty yards was composed of greasy red mud. The back wheel began to spin, and after hesitating for a few minutes, which seemed like hours, it finally began to bite again, and after sliding about fifty yards we got on to *terra firma* once more and off we went.

From Trow Hill we had a fine run on to Lyme Regis. After lunch on the sea front, we climbed out of Lyme Regis on second speed, and went on through Bridport to Dorchester. Thence through Bere Regis we made our way to Poole, rode through Poole Park, and on to Sanbeds. What a fine spot this must be for a summer holiday! The breeze off the sea was delightful. We had just started off again when, with a loud report, the sidecar tyre went for the second time. I soon had it repaired so that it would take us on to Southampton, but at Bournemouth I purchased a spare Dunlop to put on the next morning before starting. I should say that the sidecar cover was put on at Easter. It was a clearance cover, and cost only 10s., and I had a new one at home waiting to put on, but thought we should just manage to get through.

We arrived at Bournemouth at 4.50, where we had arranged to have tea with friends. Leaving here at 7 p.m., we arrived safely at my father's home in

The writer of the accompanying article and his wife in the  $3\frac{1}{2}$  h.p. Sunbeam that served them so faithfully.

**A Thousand Miles Tour in Nine Days.—**

Southampton at 8.30, having had a delightful run through the New Forest.

On Friday morning we were up early and took the morning boat to Cowes. It would not be amiss before the next T.T. race to persuade the directors of the Isle of Man Steam Packet Co. to pay a visit to Southampton and see how things are done there.

From Cowes we cut across to Ninon Point, and thence worked our way round the coast to Ventnor, and so to Shanklin for lunch. After a look round here, we made our way through Sandown and Ryde back to Cowes, just in time to catch the four o'clock boat to Southampton.

On Saturday, at two o'clock, we set off for West Drayton, near Windsor, to spend the night with my brother-in-law.

We had a fine run after leaving Winchester through Basingstoke. What a glorious stretch this seventeen miles is! Then on through Wokingham and Bracknell, arriving at West Drayton at 5.30, having accomplished sixty-eight miles with one stop of five minutes.

The next morning, Sunday, we set off promptly at 9.45 through Windsor to Reading, and arrived at St. Luke's Hospital at 11.20, where I had arranged to see one of our Sunday School boys who had been in hospital some months and was expecting his discharge. After giving and receiving various messages, and enjoying a smoke, we left our young friend at twelve. We now made our way by the river side, through Goring and Wallingford, for Abingdon. No one here seemed to know where Burcoates House Hospital was, so we rode to the Abingdon Hospital. There the matron told us we had passed it six miles before reaching Abingdon. Retracing our steps, we

found a second patient delighted to see us. Leaving Abingdon, we were soon at Oxford, and then went on to Brackley, where we had tea. Then through Towcester and Northampton to Market Harborough, where we put up for the night at 8.30. On Monday morning we left Market Harborough at 9.15, and ran through Leicester and Loughborough to Nottingham.

From Nottingham we took the Mansfield Road and then cut off to Ollerton, through the Dukeries and Worksop to Doncaster, arriving there at 2.30. After a meal, we left Doncaster at 3.30.

**A Satisfactory Machine.**

At 8.15 the Sunbeam was safely garaged for the night, having run slightly over 1,000 miles on five gallons of petrol and thirteen gallons of white spirit. The only trouble had been the two punctures in the sidecar cover. Had I fitted a new one before starting I do not think we should have had to stop for even that. The Clincher de Luxe on the front wheel and the Bates extra heavy on the back were not touched. The Bates, of course, has numerous cuts and gashes, but I am sure will run at least another 1,000 miles.

Many of my friends said it was impossible to arrange a timetable such as the one I drew up. Yet we were never more than twenty minutes out anywhere, apart from our running beyond Burcoates Hospital by mistake.

The Sunbeam is absolutely reliable. I have the original chains still running after 9,000 miles, and on measuring with the spare one I have always carried I find the long chain has stretched only a quarter of a link. In pre-war days with belt drive I used to use six belts a year. The only alteration made to the Amac carburetter was to fit a fine gauze in the induction pipe.

G.W.B.S.

Passing through a typical Oxfordshire village.

# LETTERS TO THE EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Herford Street, Coventry, and must be accompanied by the writer's name and address.

## ORIGINALITY IN MOTOR CYCLE DESIGN.

Sir,—Concerning the article in last week's number on the Big 4 Norton, I think the fact that a decompressor is not fitted to this model shows the lack of originality prevalent in the Birmingham school of motor engineering. London, Bristol, and the Bradford district produce the most original machines, and do nearly all the pioneer work.

To the London district we owe the A.B.C., Zenith, and the Blackburne. In Bristol, Messrs. Douglas, after a long and uphill battle, have established the flat twin in the motor cycle world.

The Blackburne has given the single-cylinder machine a new lease of life, in the face of its rivals, the flat and V twins. To the P. and M. we owe the decompressor; to the Scott the twin-cylinder water-cooled two-stroke and the open frame—the frame of the future.

Usual disclaimers.

J. W. MATHEWS.

## ACTION AND REACTION ARE EQUAL AND OPPOSITE.

Sir,—I trust that the following explanation *re* action and reaction will solve the difficulty raised by your correspondent, Mr. Rae, in your issue of August 16th.

In fig. (a) we see the state of affairs from the road's point of view, which, as has been stated, is that the road experiences a backward force P. Fig. (b) shows the force acting on the wheel, namely, the forward reaction R. The important point to notice is that although the reaction R is equal in magnitude to the action P, yet the wheel is acted on *only* by the reaction R. The action P expends itself on the road, and does not interfere in any way with the effect of the reaction in pushing the machine forward.

MOHANDIS.

## THE SINGLE V. THE FLAT TWIN.

Sir,—In *The Motor Cycle* of July 26th last appears a most interesting letter by "Road Officer" on this subject. May we—two Wireless Section officers, whose means of transport is the motor bicycle—be allowed space in your paper to endorse heartily the opinions of "Road Officer," and to give a few of our experiences in order to support our views?

Both of us were enthusiastic motor cyclists long before the war, and both have owned various types of machines, including singles, V twins, and flat twins. Our experience out here includes six months' winter riding on the Somme, over mud tracks, further forward than the "roads" which even D.R.'s have to tackle.

At this time we had in the section two flat twins and one single, all of the well-known W.D. type. All three machines were comparatively new, and were well cared for. The flat twins were entirely unsuitable under these conditions. They would frequently "konk" to a standstill, on low gear, and on the level, simply from lack of power to plough through the mud. Probably a lower gear and greater clearance between tyres and mudguards would have helped matters; but even then the fact would still remain that these little engines are under-powered for such heavy work, and have to turn over at a high speed on low gear for miles on end. This inevitably spells overheating and rapid wear.

For real hard work under these conditions—which none could imagine without actual experience—the small flat twin as we know it to-day is not a success, in our opinion.

We now have five singles and no twins, thanks to the good offices of our supply column. One of the twins broke its frame completely, and the other was exchanged for a single owing to a badly twisted frame. Neither machine had seen six months' road service, when it was "cast."

And what of the singles? Their behaviour has been beyond praise. Never once have they let us down; never failed to plough their way through the worst mud, and even when dripping with slush and water from the tank downwards; never a misfire.

On really good roads—we scarcely know these, riding in the forward area—the flat twin is probably slightly more "silky," owing to its excellent engine balance; but on bad roads the heavier machine holds the road better, and is far more comfortable.

But cannot we settle definitely this question as to which is the better type of engine for really heavy work, the 2½ h.p. flat twin or the 3½ h.p. single? Through the medium of your paper, we think overwhelming evidence could be produced in favour of the single, from those who have handled both types of machine in the most severe reliability trial ever held.

We do not know how many D.R.'s there are out here, but their names must be legion. From our own observation, it would seem that a large percentage read *The Motor Cycle*.

We suggest, then, that any D.R. who has ridden both types of machine, in the forward area, and who has had at least six months' riding experience on any front, should address to the editor a postcard, bearing the inscription "Single" or "Flat twin" to indicate his choice of machine for all-round work on active service.

At a date, to be named by the Editor, the number of "votes" on both sides shall be published in *The Motor Cycle*. Surely this is a fair "poll." Will you undertake it, Mr. Editor? The result should be interesting and instructive, and we hope that every D.R. who reads this letter will send his postcard.

TWO R.E. LIEUTENANTS.

B.E.F.

[We shall be pleased to fall in with our correspondents' suggestion and to publish the result of the votes given to each type two months hence. Every postcard must be duly signed.—Ed.]

## PETROL ECONOMY.

Sir,—Having read in your issue of August 23rd the letter of "Disgusted," may I say I have been treated in exactly the same manner? I twice applied for a permit for two gallons a month for three months, but was refused on both occasions for the same reason as "Disgusted."

I am in a small business doing work of national importance, which I pointed out to the Petrol Control Committee, and while I am working at my trade, my workshop facing the main road, I see a great number of cars, packed with luggage inside and out, and ladies and gentlemen inside, off in the direction of the seaside on pleasure bent for the week-end. Sometimes a Red Cross car contains the owner and his wife and luggage off for the week-end. One week-end I met a car marked Squadron No. 3. This also was loaded with what appeared to be a week-end party.

I ceased using my motor cycle for some time, then I found it would be a benefit to me to use it, so I applied for a petrol permit, which was refused, and after taking out a driving licence I only drove about six times in the year, but I shall not renew it until such times as I am able to use it more.

SUSSEX.

Holmwood.

### THE SMALL V TWIN.

Sir,—What has the light V twin done that it should be left out of the flat twin controversy? I mean the 3 h.p. or 3½ h.p. type. After a varied collection of singles, flat twins, and large V's, I fail to see in what respect it is excelled for the soloist for that very smooth running that is claimed by the flat twin owner. A. G. PEMBERTON (CARR.).

### THAT HOT SPOT.

Sir,—Re "Chinook's" query. The fact of the underside of the piston being made up with carbon very quickly should supply the answer. If "Chinook" were placed in an iron room immediately adjacent to a similar room in which a roaring furnace was situated he would quickly realise where crank case heat comes from—if he survived! Oh, those experts! J.W.

### PETROL WASTE.

Sir,—We get very frequent visits from airmen. They travel fifteen to twenty miles over very hilly country in big lorries, large cars, and motor bicycles; on Sundays and week days they come, but always in fine weather.

It is said "here" that petrol is used "there" to wash the greasy clothes in.

Why this waste when business people are so very strictly limited and have to resort to all sorts of dodges to keep their machines running at all? FAIR PLAY.

### HOW TO HIT A COW.

Sir,—I see "Ixion" has given a little advice on how to hit a dog; I should like to add a few tips on hitting a cow. Do not grip the handle-bars and steer straight, or you will return home by ambulance.

The best way is to put the wheel over to the side you wish to be thrown. By doing this, and falling over on that side, you will be shot clear of the cow, machine, and handle-bars when the cycle strikes the beast.

As riders should hug the side of the road when passing cattle one can usually land on a grass patch—but it is as well to be insured. NINE LIVES.

### AVERAGE SPEED.

Sir,—I have just read "The Critics" on "Average Speeds" in your issue of July 19th. Over-estimation of speed runs back, in my experience, to the earliest days of the bicycle; and I expect that even the Celeres—the fast men of Roman days—when they pulled up at the Corona et Anchora for a beer—or was it ambrosia they drank?—told the same tough yarns about their chariot averages. I can imagine the old landlord hitching up his toga in disgust, and growling in an undertone, "*Humanum est errare*." There, those are about all the Latin tags I know; and having more or less successfully worked them in, I wipe the perspiration off my heated brow and proceed. Sailing under no false flag, I at once acknowledge my nationality—Australian, which takes me back in spirit to the other side of the world, to that great land where the sun shines and shines, while we sweat and wish to goodness it would rain.

In the early days of the Coolgardie goldfields I was a bicycle express rider. In those days there were no telegraphs on the goldfields, and the bicycle was the only medium of rapid communication between the various centres. The pay was big, and you can guess we rode long hours.

One day, when at the top of my form, swinging along a winding camel pad, I had running through my mind some of the yarns (complimentary term) that had been told me by other riders about their average speeds. My machine—a Humber racer, 91in. gear and 7in. cranks—was the best procurable; and being fitted with a cyclometer, I determined to test the statement of one man, who said he had averaged twenty miles an hour for four hours over bush tracks. Taking the time by my watch, I stuck to it as hard as possible, and made 19½ miles in the hour. I knew then that man had lied, and ever after listened coldly to "average" stories. I had my first motor cycle in 1897, and since that long-past year I have ridden and sold many makes. The "average" yarns grew with the increase of motor cycling to impossible altitudes, until the ordinary road riders were beating the road racing men—with their mouths. A little sprig of a curate came into my garage one day with his roadster Triumph, and told me he had averaged 50 m.p.h.

from Northam to Perth, a twisty mountain road. The best racing average is 46½ m.p.h. for the same road.

However, let us dismiss the "average" fiend—from this letter, at least. Let me tell you a car-story which, without having much point, will at least illustrate how careful a man should be with noughts. Discussing with a chauffeur one day the subject of ground clearance necessary on our roads, I ventured the opinion that 9in. was ample. He scoffed at this, and said, "I ought to know better than you, for I have driven more thousands of miles than you have hundreds." I replied, "Well, I have driven about 50,000 miles, so that puts you up to half a million. Do you still stick to it?" He left in disgust. MULGA.

Harrogate.

Sir,—Reading the paragraphs on average speed which have appeared lately in your paper, I thought I would let you know my experiences. To begin with, I have an 8 h.p. Bat with overhead valves, which is an ideal mount for speed work. My fastest long distance was—at an average, including stops, of just over 40 m.p.h.—125 miles in 3h. 5m. The

The 7-9 Bat-Jap to which the writer refers.

road was fair from Birkenhead to Cheltenham. As regards short runs, I have brought a ten and a half stone passenger on the back from Shrewsbury to Oswestry, a distance of eighteen miles, in 20m. This was on a very good road. Other runs are forty-three miles in 55m., twenty-four miles in 29m., and nine miles in 10m., from Oswestry to Birkenhead, Cheltenham to Worcester, and Cheltenham to Tewkesbury respectively. Thus as the distance increases the average speed goes down. I can get 70 m.p.g. on country runs, and about 60 m.p.g. on short runs. The machine will paddle off warm on 3½ to 1 gear, and from cold after injection, and will do about 75 m.p.h. on the same carburettor setting. May I add I have no interest in Bats, except as a satisfied user? AD 2815.

Oswestry.

Sir,—I was very interested in G. Wilkinson's letter in *The Motor Cycle* of August 23rd. I should like to inform your readers of a somewhat similar journey on a 1914 3½ h.p. N.U.T., overhead valves, fixed gear of 3½ to 1. In my opinion, thirty miles can be easily maintained. Last September I went from Didsbury (Manchester) to London (181 miles) in 5 hours 35 mins., with only one stop to repair a puncture, which took me 15 mins. The actual riding time was 5 hours 20 mins. I did not stop for any refreshments on the way. The average speed, including stop, was 32 m.p.h. The return journey was accomplished absolutely non-stop in 5 hours 15 mins., which averaged out at 34½ m.p.h. The machine went splendidly the whole journey; the petrol consumption was equal to 95 m.p.g. (the tank holds a little over two gallons, so I had no need to replenish on the road). The machine at that time had to its credit a matter of 15,000 miles, and had had no replacement of any kind. This journey was not a mere flash in the pan, as I used to go regularly from Didsbury to Blackpool, via Bolton and Preston, a distance of 54 miles, in 1 hour 40 mins.—32½ miles per hour, and over Lancashire roads, which, as everyone knows, are vile. No matter on what journey I go, I always estimate to equal thirty miles per hour. The machine, although used rather roughly, has now about 25,000 miles to its credit, and is receiving its first overhaul since new.

These few instances show that a well-tuned machine is quite capable of doing good speeds. Not many horizontal twins of  $3\frac{1}{2}$  h.p. can show much better records; not a replacement in 25,000 miles or a single bearing renewed. I myself am no lightweight, scaling somewhere about 12 st. 10 lb. Usual disclaimer.

R. M. WHITEHEAD, SEC.-LT. R.F.C.

#### EXCESSIVE CHARGES.

Sir,—I recently required some new pinions for a well-known three-speed hub gear, and invited quotations from two firms who advertised that any gear parts could be supplied from stock. The two quotations differed very little, but appeared to be excessively high, so I asked the makers for a quotation, and soon received a *pro forma* invoice, which showed the other quotations to be 125% and 150% in advance of the makers' price, which was 33 $\frac{1}{3}$ % in advance of pre-war price! It is time this profiteering in the motor cycle trade was stopped, and the firms shown up.

AWAKE.

Gainsborough.

#### BENZOLE AS A MOTOR FUEL.

Sir,—I notice in your issue of August 23rd a letter by "F.E.S.," asking for the freezing point of benzole.

Benzene (*i.e.*, the pure compound forming the bulk of benzole) has a freezing point of 0°C. This property is made use of in the purification of benzene.

I have myself experienced trouble in winter by benzole freezing, but this can be eliminated by the addition to the benzole of higher boiling point compounds of the same series, such as toluol or solvent naphtha.

The freezing point of petrol is far below natural temperatures obtained at any time in this country.

L.A.S.

Knottingley.

#### PILLION RIDING.

Sir,—In your issue of August 23rd I notice a further reference to pillion riding, concerning the added responsibility of the driver in the event of a smash. It is just because of the slight additional risk, when the necessity for rapidly swerving arrives, that, in a recent communication, I strongly advocated that the passenger should sit as close, in reason, to the driver as the pillion seat will allow, passenger to be lighter in weight than the driver, and the former to retain a firm grip of the latter's belt, which should be tightly adjusted. The risk, if any, will then be reduced to a minimum; also it will be found that the added weight of a passenger will actually steady the machine when travelling.

VIC.

Golder's Green.

#### SIDECAR V. RUNABOUT.

Sir,—Why a light three-wheeler should not be vastly superior in every respect to a big twin sidecar outfit, I absolutely fail to see. I will not go into details of design, but, with the same engine, gear box, and transmission as, say, the A.J.S. combination, built into an underslung ash chassis, supporting a sporting three-ply wood body, I think a three-wheeler would be a huge success.

I have often approached my friends about such ideas, but have always met with the same old rebuffs. The chief prejudices seem to be:

- (1.) Ugliness on account of three wheels.
- (2.) Inaccessibility of back wheel.
- (3.) Air-cooled engines would overheat owing to the sheltered position.
- (4.) Three-wheelers shake to pieces.

A word or two on the above faults.

(1.) It does not seem to occur to sidecar owners prejudiced against three-wheelers that sidecar combinations are also three-wheelers of a kind. "Oh! but that's different," they say. It is candidly admitted that the sidecar combination is the ugliest and most unmechanical modern passenger vehicle on the road. In my opinion, a Morgan is far more pleasing to the eye than any £120 sidecar combination.

(2.) An A.C. Sociable back wheel is just as accessible as, if not more so than, the average motor cycle back wheel. Surely it is a comparatively simple thing to design a quickly detachable back wheel for a three-wheeler with hinged back mudguard.

(3.) If an air-cooled engine is a success in the modern heavy combination, with its broad front mudguards causing almost a vacuum wherein the cylinders must disperse their

heat, it stands to reason that the same engine in an open bonnet, with nothing to obstruct the air, must be a success also. Of course, I am taking it for granted that the running conditions are practically the same, and that the ratio of weight to power is also identical.

A vehicle that is built up as a complete unit is far superior to a motor cycle and sidecar. There is far more risk of sidecar couplings breaking than chassis members on a properly designed three-wheeler.

There are heaps more advantages suggested by "More Comfort," and I hope his letter will at least stir up conventional manufacturers' ideas. I do not blame manufacturers so much, because undoubtedly it is a big risk to attempt to compete against the sidecar market as it stands to-day, but nevertheless the Scott people have evidently thought it worth their while to do so. I do not think they will be disappointed.

I am fortunate enough to receive *The Motor Cycle* regularly, for which favour I am indebted to a fair, blue-eyed flapper, whom I hope some day—but I'm not telling everybody!

Just one more point. My companion D.R.'s and myself enjoy your military notes immensely, and there is an eager grab from all sides when the old blue cover reveals itself from out of its wrapping.

(L.-CPL.) L. S. COMMON, A.S.C., M.T.

#### SPARKING PLUG DESIGN.

Sir,—I have been following with great interest the correspondence you have published on the above subject from time to time. From all the letters you have published, and from my own experience, I think that there are now only two points in plug design about which there can be any doubt. They are: (1) What temperature should a plug be allowed to reach whilst working? and (2) should a plug be of the single or multi-point type?

To my mind, "A.W." fully explains the fact that, so long as a plug does not get hot enough either to damage its porcelain insulator or burn its points, it is not too hot. As to whether a plug should be single or multi-pointed, your correspondents seem to differ in opinion.

I always favour the single-point plug myself. My one great reason, that I have not yet seen advanced by any of your correspondents, is this. When a point receives a high voltage electrical charge, such as does the central electrode of a plug, before the gap can be broken down and the spark occur, an electrical discharge takes place from the point to the nearest earth. Now if a plug has one insulated electrode and, say, three earthed electrodes, there are three paths for this discharge to take, and it has been proved by experiment that it does not only take the shorter or easier path, but all of them, just as an electric current will flow through three or more wires connected in parallel, even if their resistances are not the same. Now if we take a plug with one stout insulated and one earthed electrode, there is only one path for the discharge to take. The discharge from the one point will be greater than that from any of the three mentioned above; but this helps to break down the gap sooner, and so there is not so much of the charge lost, and the result is a much fatter spark.

This difference in the spark can often, although not always, be seen, by first noting the spark with a multi-point plug and then that with a single-point plug, using the same magneto in each case.

I have myself tried this with magnetos and some of the latest types of American coil and accumulator systems, and find the difference more pronounced with the coil and accumulator than with the magneto.

I have tried many makes of multi-point plugs, but have always been glad to get back to the single-point again, and, in fact, have often cut the points off plugs to make single-point ones of them, and now I have several single-point plugs that were sold at 3s. 6d. each before the war that are still going strong after two years' hard work; also some of them have been working in engines that had nothing but steam in the water jackets when the water pump has broken down.

These observations have not been made on one or two cars, but on a whole convoy of cars, the ignition systems on which I have been looking after for some considerable time, so I have had every opportunity of looking into such things as plug trouble, and now I would not thank anybody for offering me a multi-point plug.

R.D.H., A.S.C., M.T.

## D.R.'S AND THEIR WORK.

(IN FOUR INSTALMENTS)

PART IV.—TYPES OF MACHINES. By D.R.

THE best type of machine undoubtedly for a D.R.'s work

is the mediumweight three-speed single, though for certain classes of work the two-speed lightweight horizontal twin is very suitable. There is no need for the high-powered twin. The single is simple and reliable, and quite fast enough (where the roads permit any speed) for any ordinary despatch work. The lightweight is very handy for pottering about over short distances, and it can easily be lifted over impossible places if necessary. Two or three-speed gears are absolutely necessary for some kinds of work, but, unfortunately, these are very frequently used more as a luxury. The low, wide handle-bars on any type of machine have come to stay—at least as far as the D.R. is concerned—though some manufacturers were very loth to adopt these as standard. Plenty of clearance between wheels and mudguards and stays and forks is of more importance than auxiliary mud shields when D.R.'s nearly always wear overalls. Front spring forks, though not all quite perfect, are about as good as we can get, but a perfect rear springing device would be welcomed by D.R.'s.

### Care of Motor Cycles.

Some D.R.'s machines are really well cared for and used in the most economical manner possible, but the abuse of other machines is most deplorable. I have seen machines left standing all night outside billets on the public footpath in the rain, simply because the riders were too idle to leave them in the M.T. depot and walk half a mile in the evening. Very much unnecessary wear and tear is caused through lack of a little attention in the way of adjustments, lubrication, etc.

The *misuse* of the clutch and variable gear is also responsible for a lot of unnecessary strain and wear and tear on machines. No doubt the clutch and variable gear are essential for some kinds of work, but these are used almost at all times when quite unnecessary. Only the other day I watched a young rider on a brand new Government machine coming up a slight gradient. He pulled up suddenly outside the post office in about five yards, probably to demonstrate how effective his brakes were. His business finished, he started the engine after two or three kicks, and took about three or four minutes to arrange himself gracefully, light a "gasper" and pull on his gauntlets, while the engine was racing the whole time. I naturally thought that he would continue his journey *up* the hill, though the gradient was not stiff enough to prevent an ordinary running start on top or middle gear. But no, he let in the clutch and *jerked* away in

low gear, only to turn round and go *down* the hill after all. It is nothing to see D.R.'s standing for several minutes at a time talking to pals while their engines are running the whole time, causing unnecessary wear and tear and fuel consumption. Such losses as these may seem very trifling when considered separately, but, if these practices occur with some hundreds of machines several times a day, the total wastage must be enormous. I do not for one moment suggest that this loss could be prevented altogether, but I say that it could be very considerably reduced.

### Sidecar Possibilities.

An ordinary passenger outfit might often be used for carrying officers on their duties instead of the heavy luxurious touring cars. A sidecar ambulance for one or even two stretchers might often be used instead of the large heavy ambulance vans for conveying some of the less serious cases to hospital. The commercial box carrier, as now being used so successfully at home by tradesmen for delivery purposes, might well be used for carrying light loads of up to 4 cwt. Indeed, the usefulness of these box carriers in the Army would be almost unlimited, and it is surprising to many that they have not been more generally adopted. They present what is probably the cheapest possible means of road transportation, and in many cases might even supplant the light lorries used. One frequently sees quite a junior officer as the sole passenger in a most luxurious Government car, while his journeys could be covered just as quickly in a sidecar and at a fraction of the cost. I know of a large ambulance van covering 160 miles for a single case for the hospital. The invalid was quite well enough to walk, with a little assistance, across country to the ambulance, which *had to wait* at the railway station from which frequent trains travelled almost to the hospital door.

Outside military camps and barracks one sees heavy horse transport waggons and motor lorries travelling regularly to and from the nearest station or supply depot two or three times a day. Except for the ration supply of one journey a day or when drafts are moving, the average load rarely exceeds 2 or 3 cwt. The commercial sidecarrier would effect a great saving in time and expense for this kind of work.

### THE NEED FOR PAPER ECONOMY.

The only way to ensure regular receipt of this journal is to place a definite order with your newsagent or the publishers.

*This action will enable newsagents to limit their orders to the actual number of copies required, and so effect a saving of paper, labour, and railway transport.*

# QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

## The Age Limit.

**Q.** (1.) I am under the impression that a licence for driving a motor cycle may be granted at the age of fourteen years. Is this so? (2.) Can I also drive a sidecar at this age, or am I permitted only to drive a solo mount?—B.D.

**A.** (1.) A licence for driving a motor cycle may be granted at the age of fourteen years. (2.) The type of motor cycle is not stated, therefore we assume that this applies to any vehicle registered as a motor cycle, including a sidecar outfit.

## Decarbonising.

**Q.** Would you be good enough to inform me if you consider the Cyclean process a good method of decarbonising a 6 h.p. twin-cylinder J.A.P. engine (Enfield)? I have been told that the extreme heat used is apt to distort and pit the cylinder.—P.H.

**A.** We believe the Cyclean process to be an excellent and perfectly safe method of decarbonising, though, of course, there is no way of doing this so thoroughly as by taking the engine adrift. The heat process merely removes the carbon deposit from the combustion head, the top of the piston, and the valve pockets, but it does not free the piston rings, which are generally improved by a little attention, nor does it clean the inside of the piston.

## Carburettor Choking.

**Q.** I should be glad if you would tell me what is wrong with my twin-cylinder motor cycle. It will not take open throttle, but will take the air about quarter way open. It will start all right, but will not continue to run. It slackens speed and then stops, but will pick up sometimes if I put my hand over the hot air intake. I have had the engine down, and fitted a set of new piston rings and new bushes. It consumes half a gallon of petrol for ten miles.—P.C.K.

**A.** Possibly the running of the engine will improve after it has been on the road a little longer and when the new piston rings and bushes have become run in. The symptoms which you describe seem to indicate that there is a partial stoppage in the petrol system, probably by air lock. On the other hand, the consumption is absurdly high, and we can only account for this by assuming a serious leak somewhere in the petrol pipe, at one of the unions, or that the carburettor is flooding.

## Running on Coal Gas.

**Q.** Will you be good enough to give me a little information regarding the use of coal gas as a fuel for my motor cycle? (1.)

Is the fuel suitable for a single-cylinder 4 h.p. engine with good reliability? (2.) What is the volumetric consumption for above engine (approximately), using coal gas, with a medium weight sidecar and passenger? (3.) What alteration to carburettor would be needed to give best satisfaction, and would other parts require alteration? (4.) Should I experience difficulty in starting with this fuel in cold weather?—G.H.F.

**A.** (1.) We do not think that the use of coal gas is applicable to motor cycles. Petrol engines will run on it, but they become much hotter than on petrol, and the difficulty lies in carrying a sufficient volume of gas aboard the machine. It is practically impossible to carry on a sidecar frame more gas than would take the machine approximately fifteen miles. (2.) About eighty-five cubic feet of coal gas are equivalent to one gallon of petrol.

(3.) We do not think any alteration will be necessary to the carburettor. It would simply be used for governing the air supply, and the coal gas could be taken in by a small pipe connection directly to the existing induction pipe. (4.) No, you would not be so likely to experience as much difficulty in starting in cold weather as with petrol.

## Pre-ignition.

**Q.** I have a 2½ h.p. Calthorpe-Precision. After the machine has run from one to two miles it gets fearfully hot. It uses a large quantity of petrol, and on opening the air lever past the throttle the engine misfires, and will only fire regularly when air and throttle are together, except when at a high speed, when the air lever can be opened a little. The jet is No. 30.—A.A.

**A.** We should recommend you to try another make of plug, as that which you are using may be causing pre-ignition. Also try the effect of a much smaller jet; experiment with various sizes until you get the best results. We presume the compression is normally good.

## A ONE-HORSE POWER PUSH.

The Auto-wheel is an adaptable little unit, and though, of course, much under-powered to propel a tandem tricycle, the owners find it a great help on their journeys. By its aid they can average twelve miles an hour with comparatively little exertion.

**For Sidecar Use.**

?

I have a 1912 single-gear clutch  $3\frac{1}{2}$  h.p. Triumph, and I want to fit a Watsonian or other lightweight sidecar; weight of two persons, 17 stone. Will the machine do it, and would fitting a Philipson pulley improve matters.—H.G.C.

We do not think you would find a single-gear machine with direct belt drive very well adapted to sidecar use, but the addition of a Philipson pulley would help matters immensely. You would probably obtain better satisfaction by selling your present mount and buying a good second-hand outfit, while the expense might be but little greater.

**A Flat Twin and Heavy Fuel.**

?

I should appreciate your advice with regard to carburation in connection with my 1917 6 h.p. flat twin. The machine has an automatic carburetter. This carburetter was satisfactory with petrol, but when I commenced to use substitute the engine would not accelerate from the slow tick-over obtained on the pilot; when the throttle was opened the engine would revolve a few times, misfire, back-fire in expansion box, and blow back through the carburetter; then it would stop. I increased the diameter of the choke tube, thinking more air would cure the disorder, but the results were worse; and even with pure petrol the engine performed exactly as with substitute. I then decreased the diameter of the choke tube till it was about 15% less than when the machine was delivered, and the engine accelerated fairly satisfactorily. Though the machine has since done 500 miles over rough Welsh country—including some short pitches of 1 in 5 and, I think, 1 in 3 (third gear) with heavy load—the acceleration is sluggish, and I have had machines of another type, but the same horse-power, go past me. Of course, if the other machines have petrol going through the carburetter instead of paraffin (as I have) I cannot expect to attain the same speed. I find that if I open the throttle too quickly the engine will not pick up (from pilot to main) satisfactorily, but misfires and blows back through carburetter; however, this does not occur when I accelerate slowly. (1.) Would you recommend me further to reduce diameter of choke tube (inside diameter)? (2.) Or would a larger jet be the better adjustment? (3.) As an alternative, I have been thinking of fitting an automatic multiple jet carburetter, which I found a very great improvement to my Scott. Could I expect better acceleration and more power and speed if I fitted one to my 6 h.p. flat twin?—A.S.L.

We have experienced the same trouble as you speak of with flat twin engines using heavy fuel, and we doubt very much whether you will be able to remedy it. To obtain a slow tick-over with paraffin or substitute is, we believe, almost impossible. (1.) This rather depends on your fuel consumption. If you are doing a good mileage per gallon

you might try the effect of still further reducing the size of the choke, but we would not recommend you to do this if your fuel consumption is heavy, as the liquid fuel would probably get past the rings and injure the bearings. (2.) The foregoing also applies to size of jet used. (3.) You would probably experience the same faltering with a multiple jet carburetter. It would be a good idea to lag the induction pipe and to fit an efficient hot air intake to the carburetter.

**Overheating and Knocking.**

?

(1.) I have experienced overheating and knocking on my 1916 T.T. Rover, and although recently dismantled it is almost as bad as before. Do you think this could be due to a choked silencer? It would seem that there must be a great deal of back pressure from this silencer, as the gas has to pass two complete right-angled corners, and so perhaps a slightly choked box would have the effect of giving more back pressure on this type than on others. (2.) Are these machines inclined to run unusually hot? (3.) The crank case release consists of a small hole through the centre of the Philipson pulley, air being alternately forced out and sucked in as the piston descends and rises. A large quantity of oil is constantly being forced out, making engine, machine, and rider's boots very oily. Can you tell me how to overcome this? I have drilled a hole between the tappet guides in the crank case, and have led a copper pipe to the underside of the crank case, but this is unsatisfactory, as the pipe gets choked up with dust, etc.—J.H.J.

(1.) It is almost impossible for this pattern of silencer to choke. The silencer is well designed, has an almost total absence of back pressure, and is one of the most efficient on the market, as was proved by the A.C.U. Silencer Trials in 1913. It is more likely that the trouble is due to too high compression, which may not suit the rather poor petrol we have at the present time, and may be cured by fitting a plate about one-sixteenth of an inch thick between the bottom of the cylinder and the top of the crank case. (2.) These machines are not usually inclined to overheat. (3.) This is a disadvantage of this pattern of relief valve. The trouble could be overcome by plugging up the hole and fitting a one-way relief valve to the

crank case, as you suggest. Your idea should be quite satisfactory, and we cannot understand why the pipe should get choked up as it does. Perhaps it has rather too small a bore.

**Cyclist and Motor Cyclist.**

?

Is it possible for a man to ride and become a good rider of a solo  $3\frac{1}{2}$  h.p. motor cycle without previously ever having ridden or learnt to ride a pedal cycle? Could he become as good a driver as one who has formerly been a cyclist?—S.W.

Certainly the good motor cyclist is rarely the man who has been an exceptional pedal cyclist. To learn to ride a motor bicycle, however, it is better to have begun on a pedal cycle, but the riding of the two is quite different, as the successful motor cyclist must have a thorough knowledge of his engine, should know how to get the best out of it, in addition to being able to keep a straight course and ride over difficult places. To begin with, an attempt should be made on an old machine, fitted with pedals and the drive disconnected, so that the balance of the two-wheeler may be acquired.

**RECOMMENDED ROUTES.****LEEDS TO THETFORD.—H.W.P.**

Leeds, Doncaster, Retford, Tuxford, Newark, Sleaford, Swineshead, Long Sutton, King's Lynn, Stoke Ferry, Mundford, Thetford. The distance is approximately 154 miles.

**BOURNEMOUTH TO ILFRACOMBE.—E.E.J.**

Bournemouth, Wimborne Minster, Blandford, Sherborne, Marston Magna, Langport, Taunton, Milverton, Wiveliscombe, Bampton, South Molton, Barnstaple, Ilfracombe.

**ONGAR TO CHESTER.—G.H.A.**

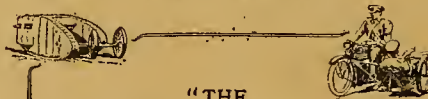

Ongar, Harlow, Hertford, Hatfield, St. Albans, Leverstock Green, Berkhamsted, Tring, Aylesbury, Bicester, Banbury, Stratford-on-Avon, Alcester, Headless Cross, Bromsgrove, Kidderminster, Bridgnorth, Wellington, Hednet, Whitechurch, Chester.

**NEWCASTLE TO LOWESTOFT.—R.D.F.**

Newcastle, Durham, Darlington, Northallerton, Boroughbridge, Wetherby, Aberford, Ferrybridge, Doncaster, Bawtry, Retford, Tuxford, Newark, Leadenham, Sleaford, Swineshead, Long Sutton, King's Lynn, Swaffham, Dereham, Norwich, Thorton, Beccles, Lowestoft.

**A Route to avoid Brentford.**

The following route from London on to the Exeter road is suggested by a correspondent. Instead of going through Brentford to Hounslow, the Uxbridge road should be taken as far as Southall, when turn to the left down South Road, over the railway, where turn right down North Hyde to Cranford, then turn right down the Bath Road past "The Berkeley Arms" to the first turning on the left to Bedfont, where the right-hand fork should be taken down the Staines road. The *détour* involves an extra distance of about three miles.

# MISCELLANEOUS ADVERTISEMENTS.

## PRICES.

**ADVERTISEMENTS** in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to **ILIFFE & SONS Ltd.**, and crossed **& Co.**

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

## NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

## DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

## SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

## MOTOR CYCLES FOR SALE.

### Abingdon.

**ABINGDON** King Dick, 4h.p., 2 speeds, handle starting, fitted with lamps, horn, generator, and new tyre; £20.—Wellbry Motor Garage, Woodford Rd., Forest Gate. 'Phone: 309 Stratford. [7340]

## DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

## MOTOR CYCLES FOR SALE.

### A.J.S.

**1916** 2½h.p. Solo A.J.S., splendid condition, running order throughout, 3-speed, kick starter, tyres perfect, usual accessories, mileage 1,500; seen London; £45.—P., 19, Palace Gate, S.W. [7364]

**1916** 4h.p. A.J.S. Combination, clutch, kick starter, 3-speed, Miller head lamp, mechanical horn, good tyres, tools, spares; expert examination; lowest £85.—Box 1,196, c/o The Motor Cycle. [X4755]

**A.J.S.** 2½h.p., 1914, 3-speed, clutch, T.T. bars, P. and H. head lamp and generator, rear lamp, tools, sound tyres, machine perfect throughout; £40.—Advertiser, 156, Gt. Portland St., W.1. [7563]

# Taylor's

**The 'MARVEL' STEAM VULCANIZER.**

Both Covers and Tubes of any size can be effectively Vulcanized. A permanent repair is guaranteed. Saves expense of sending tyres away, and a great saving in time.

Anyone can do it. Ten days' approval against remittance. Money returned, less carriage, if not satisfied. Price—motor cycle and cycle car size, 13/3; car size, 25/-. Carriage paid.

**AN OWNER'S EXPERIENCE:**  
Smithy Brook Middletown, Wakefield, Yorkshire, July 28/17.  
To H. Taylor & Co., Ltd.  
Dear Sirs,—Having tested the Steam Marvel Vulcanizer you sent to my son, F. Beaumont, I find it all you claim for it. I have repaired all his inner tubes and mine successfully, and I have also repaired outer covers by putting bits of tread on where it has been worn to the canvas. I have never seen or used a vulcanizer before, and I made a success of the first job.  
Yours faithfully, A. BEAUMONT.

## MOTOR CYCLES FOR SALE.

## Sunbeam.

**SUNBEAM** 1915 Combination, 6 h.p., fully equipped, mirror, Cowey speedometer, perfect condition, 1,906 miles.—Morse, 37, Replingham Rd., Southfields, S.W. [X4802]

**1915** Sunbeam, 3½ h.p., black, gold, 3-speed, h.b.c., latest equipment throughout, mechanically perfect, excellent order; £60.—Robinson's Garage, Green St., Cambridge. [7464]

**SUNBEAM**, 3½ h.p., 1917, service green, £15 sidecar to match, all accessories, 2 spare valves, tyre, 2 tubes; £90, no offers.—Aitchison, 8, Lancaster Rd., Birkdale, Southport. [X4802]

**1916** Sunbeam, 3½ h.p., black, gold, 3-speed, h.b.c., 2 lamp sets, mechanical horn, with Skiff Millford sidecar and storm apron, 1,000 mileage, new condition, £87/10.—Robinson's Garage, Green St., Cambridge. [7463]

**SUNBEAM** 1914 3½ h.p. Combination, 3-speed, hand clutch, Canoelet Skiff sidecar, Lucas lamps, speedometer, watch, exceptional condition and speed; £66/10; seen London.—Lacking, 19, Bridge St., Leighton Buzzard. [7546]

**1916** 8 h.p. M.A.G. De Luxe Model Sunbeam Combination, perfect, Lucas dynamo lighting set, electric horn, speedometer, spare wheel, tyre, new tyres, wind screen; 120 gns.—Box 1,193, c/o The Motor Cycle (1). [X4771]

**SUNBEAM**, genuine 1917 3½ h.p., 3-speed model, with kick starter, semi T.T. bars, Lucas accessories, speedometer, ridden approximately 500-600 miles only, quite as new.—Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green, N. [7419]

**LATE** 1915 Sunbeam Combination, 3½ h.p., Splendid, B. and B., new July, electric lighting, 3 bulbs, 2 accumulators, Lucas horn, 1 spare outer, 3 spare inner, timepiece, Stewart speedometer, Oris triple sliding screen, knee-grips, luggage carrier, 3 aprons, tools, mirror, 9 months' insurance; £80, complete; want to buy 5-seater, 1916-1917.—Johnston, Seddon House, Garston, Liverpool. [X4765]

## T.D.C.

**De Luxe T.D.C.**, 1916, 2½ h.p., just been overhauled; £25.—W. and H. Motor Co., Ltd., 287, Deansgate, Manchester. [7189]

## Triumph.

**3** h.p. Triumph, Grade gear, fine order; £12/15.—373, Katherine Rd., Forest Gate. [7447]

**JUNIOR** Triumph, 2-stroke, 2-speed, new condition; cash £42/10.—Goodman, Bletchley, Bucks. [7335]

**JUNIOR** Triumph, 2-stroke, lamps, horn, and accessories; £20.—R., 60, East Dulwich Rd., S.E. [7541]

**TRIUMPH**, 3½ h.p., 1913, 3 speeds, in real good order; £33.—Percy and Co., 337, Easton Rd., London. [7572]

**TRIUMPH**, 1914, 4 h.p., 3-speed, C.B. combination, just retushed; 45 gns.—J. Rogers, 690, Liverpool Rd., Irlam. [X4761]

**TRIUMPH**, 1913, 3½ h.p., 3-speed, sidecar, hood screen, grid, good tyres; £37.—108, Greenfield Rd., Harborne, Birmingham. [X4544]

**1911-1912** T.T. Triumph, in splendid order, fully equipped; bargain, £17/10.—Appleton, 32, High St., Harlesden, London. [X4861]

**1914** 4 h.p. Triumph, 3-speed, good tyres, excellent condition, 2 lamp sets, horn; £42.—Robinson's Garage, Green St., Cambridge. [7467]

**1912-13** Triumph, 3½ h.p., 2-speed, free engine, in good order, lamps, horn; £23, near.—J. Davidson, Stuartfield, Mintlaw, Aberdeenshire. [7305]

**TRIUMPH**, 1910, 3½ h.p., with Brampton gear, £19/10; 1911 3½ h.p., spring forks, £22/10.—Motor Exchange, Horton St., Halifax. [7083]

**BABY** Triumph, as new, Lucas set, Bosch, Clincher and Dunlop; £52. Wanted, 4 h.p. Triumph solo.—Lawley, 68, Market St., Penzance. [X4355]

**1911** Triumph, 3½ h.p., 2-speed, Bosch mag., free engine; £16.—Tobaccoist, Railway Approach, Tadworth, Surrey. 'Phone: 242, Burgh Heath. [7232]

**TRIUMPH**, late 1913, T.T., specially tuned, excellent condition; great bargain, £23.—Longman Bros., King St., Acton. 'Phone: 1578 Chiswick. [7500]

**TRIUMPH**, 3½ h.p., Sturmey-Archer 3-speed, with Dement coachbuilt sidecar, P. and H. lamp, Lucas horn, good condition; £32.—Freestone, Grocer, Littleover, Derby. [7439]

**TRIUMPH** (late 1914), 4 h.p., clutch, Philipson, Binks, speedometer, runs on paraffin, splendid condition, unused 18 months; £38.—Hole, St. Catherine's, Mids., Hants. [7330]

**TRIUMPH**, 3½ h.p., carefully used, cylinder ground, new piston, tank re-enameled, semi T.T. bars, new belt, lamps, horn, spares; £24/10, offers.—48, Derwentwater Rd., Acton. [7349]

**TRIUMPH**, 1914, 4 h.p., coachbuilt sidecar, perfect throughout, Lucas horn, speedometer, spare tubes, and accessories; sacrifice £37.—Fellows, Victoria Villa, Stanningley, Leeds. [X4528]

**TRIUMPH**, with sidecar, 3½ h.p., mag., 2 speeds, Lucas large head lamp; any trial; £25; exchange arranged.—Wandsworth Motor Exchange, Ebner St., Wandsworth (Town Station). [7601]

**RIDER TROWARD** and Co., 31 and 78, High St., Hampstead.—1914 4 h.p. Triumph, 3-speed, 38 gns. with 1916 coach sidecar 47 gns.; 1913 T.T. Triumph 23 gns.; 1913 Triumph, clutch, 23 gns.; 1911 standard Triumph, 16 gns. (1) [7421]

## HENRY NOTTBECK

The only Harley-Davidson Agent  
with Milwaukee Factory Experience.

## SECOND-HAND HARLEYS.

1916 J and Sidecar, fine order ..	£90 0
1916 F, solo, new tyres, splendid order .....	£70 0
1915 M.A.G. Model, overhauled ..	£60 0
1915 J and Sidecar .....	£62 10

## OTHER MACHINES.—Offers wanted.

<b>ABINGDON</b> , T.T., 1912.	
<b>HUMBER</b> , good order, 2-speed.	
1915 <b>RADCO</b> .	
1915 <b>ZENITH</b> , 8-10 h.p., clutch, sporting Sidecar, fine lot ....	£65 0

## Motor Cycling and Moral.

**W**E have always affirmed that motor cycling has a healthful effect not only upon the body but on the mind, as it teaches the rider judgment, patience, and self-control, while it sharpens his wits and strengthens his nerves. We are very glad to note that this view has now been taken up in two papers in two different countries.

Glancing through that excellent publication, *L'Automobile aux Armées*, the other day, we found a special article devoted to this very subject. Commenting on the fact that the Germans at the beginning of the war counted on the nervous temperament of the French, the author of the article points out that they had forgotten the education of sport—the results of which were present in the new generation—which developed calmness of mind and *sangfroid*. The article indicated that the excitable Frenchman at the beginning of the motoring movement did not realise that one could not adjust a magneto by kicking the crank case in a temper when the engine stopped; consequently the driver was taught patience, became resourceful, and the next time the engine gave out he would quietly set to work and eventually get going again.

We now come to an article appearing in a daily paper which has not been kind to the motoring movement either on the occasion of its inception or during the war. The article in question, however, is calculated to do a considerable amount of good to the motor cycle movement. It deals with a case of several nurses who journey daily to a V.A.D. hospital in the depths of the country, the commandant of which is thankful that four of the nurses and a quartermaster have motor bicycles which enable them, though they live five miles away, to attend punctually. Further, a case is given of two girls living in the country who are engaged on important war work, who state that they could not continue their jobs—in fact, could not have undertaken them—if they had not possessed

motor cycles. These particular girls live eight and six miles from their work, right off the railway track, and neither of them could face the double journey on an ordinary push cycle, while no pony could do it regularly.

*The Motor Cycle* is well in touch with the movement from the ladies' point of view, and articles frequently appear showing the utility of the motor cycle in feminine hands and the excellent results obtained with it, but the article to which we have referred further encourages the adoption of the motor cycle by women. "Some women," it states, "who are attracted by the idea, fight shy because they think a motor cycle is too heavy for a woman to propel without endangering her strength, and too intricate to use or understand. That is quite wrong; the present-day simplicity of machines is such that the superficial intricacies can be grasped by any average woman. Mechanical mishaps may occur, but a woman can easily learn to remedy the minor troubles . . . and it may be remembered that but few men motor cyclists understand everything about their machines."

"For the rest, a motor cycle teaches a girl or a woman much that is good. It really creates a far better *moral* than push cycling. Motor cycling gives a girl a healthy and wholesome independence, and inculcates reliance and resource, while developing powers of patience and broad commonsense."

As we have stated above, we have always maintained that this is so, but it is unusual to see such enlightenment in a daily journal.

This now forces us to hark back to the subject of our leader in the issue of August 30th, when it was pointed out that it was essential that a limited quantity of petrol should be allocated to motor cyclists for their own use, because as the demand for motor cyclists engaged on war work increases, as it is bound to do, it is essential that experience should be obtained somehow, and naturally experience cannot be got without the necessary fuel.

## Life and the Open Road.

*Pleasant it is to hear the swish  
Of the water round your boat,  
Or in flannels cool in some still pool,  
To drift and laze afloat.*

*There's joy in swimming with crestless waves  
Where the tide runs deep and wide,  
And there's life away in the swift short sway  
Of a horse's steady stride.*

*But there's joy of life in the open road,  
The road that is unknown too,  
Where the endless wind that is seldom kind  
Can kiss you or cut in two.*

*A boat will rock as the sea gets strong,  
And the crested waves turn cold;  
They buffet and beat—and a horse's feet  
Grow tired—a horse grows old.*

*But with grease and oil and a little time  
Your bike is a friend that's fair;  
On valley or hill it is faithful still,  
And it always gets you there.*

*You cross the glare of a summer sun,  
You bow to the slash of rain,  
But never you find in storm or wind  
That you've given your care in vain.*

*Ah, me! the streak of the long white road  
Where the tall, dark trees flash by,  
And the heat of the day gets wiped away  
With the dusk of a twilight sky.*

*And the moon comes up from a dewy haze,  
And the damp air lends you power,  
You know you can do—the whole night  
through—  
Your thirty miles per hour.*

SOPHIE ELIOTT LYNN.

### Some Old Scandals.

THE conservatism of designers in so simple an accessory as a motor cycle stand has long been one of the blots on the industry. A great deal of pen-pricking was necessary before the trade was induced to abandon in the earlier days a triangulated girder abomination, the top of which normally carried the luggage, but was let down to serve as a puncture-repairing stand after the luggage had been removed and stacked by the roadside. This was in due course succeeded by another abomination, to wit, a stand consisting of two separate legs, attached to the chain-stays by bolts and nuts. I always carried a few spare bolts and nuts, as they littered the road on every long run. Two separate operations were required to hoist the machine, and the stand was only usable on a level surface, even supposing the legs did not bend. When sound presswork produced the scrapping of this crude notion, the trade refused to fit an automatic catch on the tail of the back mudguard, and after one had wheeled the machine off the stand, one had to walk back again to screw up the catch.

### Some Modern Needs.

THERE have, of course, been humorous interludes. There was the inventor who tried to popularise motor cycling by patenting a stand which was hauled up with the engine running, so that machine and rider were projected into sudden forward motion, with subsequent injury to the road, the machine, and the rider; he vanished when the free engine came along. Then there was the genius who invented spread-eagle side wheels, alleged to prevent skidding, and capable of being used as a stand. But, generally speaking, present-day stands are pretty good. It is true some makers still fight shy of the fly-up stand, which locks itself, and doesn't ask for a spring catch at the tip of the back mudguard; presumably, their mudguards are too heavy, or their stays too weak, so that the extra support of the stand is welcomed. Or do the Rudge people hold a genuine master patent for all devices of the kind? They are certainly streets ahead of other patterns. I think the crying need that survives our slow and clumsy evolution in this respect is a stand which will relieve users of the labour of hefting a heavyweight several inches into the air; this labour is one of the factors which have popularised the still somewhat erratic baby two-stroke. For this reason I seized with avidity on an American advertisement, depicting a slim rider hoiking a 12 h.p. twin on to its hind legs with his little finger. Underneath was the legend, "It's the roller mechanism that does it!" I put my microscope on the photograph in eager search for the details of the aforesaid "roller mechanism," but could perceive nothing of the sort; the idea

appeared to consist of a stand possessing a base sloping up towards the front of the machine in a gentle curve, so that if the owner puts his toe against the back of the stand, and pulls at the carrier with his hands, the base of the stand acts like an inclined plane. The notion may be an improvement, but I question whether the average man will find it enables him to tweak a big twin up with his little finger. Anyhow, the designer concerned has a keen eye for an aching void. Is it beyond the wit of man to devise better stands for heavyweights? Many a modern heavyweight scales nearly 4 cwt., and in many cases the weight of a sidecar is super-added. Men of over 45 are liable to serious injury in the attempt to raise such a load. If it is impossible to devise such a stand; the need would be partly met by the fitting of an auxiliary prop-stand, intended for use when the machine merely needs propping, and not lifting, leaving the existing fittings in reserve for puncture repairing and so forth. But it should not be difficult to invent a pedal lever stand which would fill the bill.

### The W.D. Oiling System.

ONE of my great disappointments as a motor cyclist was the refusal of the trade to follow the lead set it by Messrs. Wartnaby and Draper, when they brought out a motor cycle with a rational lubricating system. Readers may remember that a sump beneath the engine carried sufficient oil for several hundred miles: this was circulated by a pump, and the engine was accurately oiled: its plugs never sooted: the oil consumption was low: the crank case kept spotlessly clean: and the rider had no demands made on his memory or skill. I sighed for a W.D. machine this week, when I had to ride in succession three typical British machines, none of them too familiar, all throwing the onus of accurate oiling on the driver, and all oscillating between the twin nuisances of a hot bearing or a sooted plug. Readers know that I am not on principle an indiscriminating admirer of American motor cycles, and consider they enjoy a far greater popularity in this country than they deserve. But on this point at least they have us whacked. You can get on most Yankee bicycles and leave them to oil themselves. On the average Britisher, unless you stick to one machine and one brand of oil, you are perpetually wondering how long ago you put in that last charge of oil, or how many drops are really percolating per minute behind the miserable little greenery-gallery window of the so-called sight gauge.

### Address Wanted!

WILL the B.E.F. correspondent who recently sent me a long anonymous screed on valve timing (for which I am very grateful) kindly forward his name and address to me in confidence?

## THE ROTARY ENGINE FOR MOTOR CYCLES.

Some Claims for Consideration as a  
Motor Cycle Prime Mover.

**B**EFORE the war the rotary engine occupied a doubtful position before the public, at least nine-tenths of whom believed all such engines to be a species of jig-saw puzzle, kept running by the united efforts of specially trained engineers; while the rest, seeing that the majority of special performances in the air were done by rotary equipped machines, desired the immediate application of the type to motor cycles, without pausing to consider the difficulties, or ascertaining any details whatsoever of the machine.

During the war, however, many hundred ex-motor cyclists have taken places in the rank and file of the R.N.A.S. or R.F.C., and in so doing have come intimately in contact with that strange yet wonderful machine, the rotating engine. Now there are many great advantages which may be gained by using a rotary, and these advantages are:

Firstly, the multi-cylinder engine is much smoother than the more common two or four, not only when all goes well, but also when the engine is inclined to misbehave, because the irregular firing of one cylinder out of nine is much less disconcerting than trouble with one cylinder out of two, in engines of the equal c.c. This smoothness of running is not imaginary, and is a very real advantage, but it depends entirely on the care used in manufacture. Yet it is as easy to make a badly balanced rotary as it is a bad engine of any other type.

Flexibility is another strong advantage not brought much to the fore until recently, because, in the past, aeroplane pilots have not worried much about speed variations in the air, but were content if the maximum of 1,200 was maintained. Now, however, a good rotary can run quite slowly, and a motor cycle rotary having an ordinary carburetter would obviously prove the most flexible of all. Since flexibility is a very great advantage for motor cycle work, here the rotary gains.

Needless to say, the lightest engine for a given power is a rotary or a radial. But the radial still has certain defects of cooling and lubrication from which the rotary has been freed.

Against the multi-cylinder rotary one often hears urged the argument that the average

man could not deal with the complication of so many cylinders, and would be lost should anything occur; yet it is a fact that the seven or nine-cylindereed aeroplane rotary is one of the simplest things to strip that any man could desire, and a 100 h.p. engine, say, can be taken down while one of the normal type still is puzzling its owner. Every piece of the "inside" can be removed, inspected, or replaced in what appears to be a miraculously short time.

### Locating a Misfire.

It is quite easy to ascertain correctly which of fourteeen rotary cylinders is missing if that missing is regular, but it must be admitted that irregular misfiring is a curse to the uninitiated, while offering some small trouble even to the skilled mechanic.

Cooling troubles, the bane of the old steel cylindered Gnome, can be overcome until the rotary keeps quite as cool as the stationary water-jacketed machine, while with this advance the reliability has become such that an engine of this type can be used exactly as the ordinary one-lunged thumper, whose ever-ready propensities have been so much admired in the past.

Silencing, against which problem many people have failed, is a purely mechanical difficulty, and in an engine of such small diameter as would be a motor cycle rotary, presents fewer difficulties than one would imagine. Inlet piping is now common, and if due care be exercised to avoid some of the pitfalls set up by centrifugal force, exhaust piping could be installed with but a small loss for extra wind resistance.

A change gear, with, say, two or even three ratios in the drive, lends itself to the rotary installation, and would be necessary, since the additional problems, which arise as the rotational speed increases, are sufficiently worth avoiding, by keeping down to, say, 1,500 r.p.m.

Now, few people realise that one horse-power can be obtained for, roughly, 100 c.c., and that a nine-cylindereed motor cycle rotary might well have a bore of 40 mm. and a stroke of 50 mm., the total diameter of the complete engine being in the neighbourhood of 12 in.

This would mean a compact engine if the magneto could be accommodated, but this

The seven-cylinder Clerget rotary engine, which has mechanical exhaust and inlet valves and a separate inlet pipe from the crank case to each cylinder.

**The Rotary Engine for Motor Cycles.—**

magneto is not so easy to fit as might be thought, and only a train of gears would bring it into an accessible position without greatly increasing the total breadth of the engine.

Certainly the carburetter would project, but this would not be more so than in the case of the present Douglas, and the Douglas is none the worse for it, nor is it more uncomfortable to ride. Obviously, the engine should be slung longitudinally in order to be protected should a fall occur, and if the rotational speed be kept comparatively low the gyroscopic effect of the engine would not be noticeable when steering, as it would take a heavy weight revolving very fast to influence the balance of the motor cycle. There is a possibility that a transverse engine might be worked in for sidecar machines, as here the engine would not be likely to sustain damage from frequent falls.

Probably the Le Rhône system of valve gear with push and pull rods would make the most compact engine if the valves were placed in the head of the cylinder, while the Le Rhône connecting rod arrangement also seems desirable. One set of plugs is all that would be required, and the ignition advance pre-

sents no real difficulties, and certainly would assist slow running. A better forced oil system could be arranged in order to bring down the oil consumption which, in this type of engine, is high, but it must be remembered that oil consumption per b.h.p. hour is at present unnecessarily high on all motor cycles in any case.

**Summary.—**

Summing up, therefore, one gains accessibility, power for engine weight, smooth running, flexibility, and more even cooling, while the difficulties to be solved are compact installation, particularly of the engine's components, adequate inlet and exhaust piping and lubrication systems—all of which are purely mechanical problems.

Petrol consumption has been high for aeroplane engines, but need not be so if the machine be arranged for motor cycle work, and with a motor cycle or small car type carburetter. Therefore it would seem worth while for designers to pay great attention to this type of engine, with a view to its installation on the machine, for that blissful period which will succeed Armageddon. S.H.D.

## A FAMILY SIDECAR.

### A FULL COMPLEMENT FOR A SINGLE-CYLINDER.

TO owners of sidecars who are family men, the following brief description of a particularly roomy sidecar may be interesting. The portion of the sidecar body nearest the machine is bowed to

allow for a child's seat, and Mr. P. F. Warner, speaking from actual experience, says this design is admirable in every way. One may question whether this form is superior to the tandem seating, which is the usual method of carrying a child. The chief advantage is that the child can be snugly seated in the little "annex," and another carried on the knee or seated tandem-wise, should one, of course, be the fortunate owner of a pair of these young enthusiasts.

The photograph shows that the idea is practicable, for there are "five up" on the outfit without creating an appearance of overloading. The sidecar—which is made by the "Willowbrooke" Co., Leicester—has an extension at the rear forming a capacious locker. One drawback, we should imagine, is the close proximity of the passenger in the "annex" to the driver's elbow.

The "Willowbrooke" sidecar, showing arrangement of the seating accommodation.

A  $4\frac{1}{2}$  h.p. Harley-Davidson, to which has been attached an exceptionally roomy sidecar. Not many light cars could take a bigger load more successfully. Besides the four passengers there is a loaded locker and portmanteau carrier.

### A NECESSARY SAFEGUARD.

PRACTICALLY every motor cyclist who dabbles in the second-hand market has experienced difficulty in ascertaining the date of manufacture of the machine he has contemplated purchasing. Constantly we receive letters from readers complaining that they have been misled as to the year of manufacture of second-hand purchases; and in these days, when practically no alterations have been made season

by season, it becomes vitally necessary for makers—in their own interests, in addition to the interests of their *clients*—to adopt some means whereby the date of manufacture of their products can immediately be ascertained. The easiest and best method is, of course, to stamp the crank case, as is done by the Triumph, Velocette, and other makers. This would remove the doubts of both seller and buyer.

# DARTMOOR AS A TOURING GROUND

Some Account of the Roads, Beauties, and Antiquities of South Devon.

By H. TAPLEY-SOPER.

(The first instalment appeared on August 16th.)

THE initial twenty miles of our second Dartmoor tour takes us over a course which will be very familiar to riders in the reliability trials of pre-war days. We again quit Exeter *via* Fore Street, but on passing over Exe Bridge turn sharp to the left and soon desert the treacherous tramlines. A few yards after passing under the second railway bridge should be noticed, on the right, "Mile End Cottage," which in 1839 the immortal Charles Dickens rented for his mother and father, and where he is supposed to have written certain chapters of "Nicholas Nickleby," and perhaps of "Martin Chuzzlewit," for several of the characters in these books have been identified with local celebrities.

Alphington Church, standing well above the road, is next passed on the left, and we open out for our first rise and fall, and soon find ourselves negotiating a tricky descending right and left-hand turn which suddenly introduces us to Kennford. The "ford," which, as far as we know, is invisible, must be near, for we swerve to the right and pass across a little bridge with a nasty approach. If the dust at this point allows one to make quite sure that the village policeman is off duty, it is as well to advance the throttle for a rise of nearly three miles to Haldon Down. Telegraph Hill, the local terror in fixed gear days, is passed on the left, and when the turnpike cottage comes into sight it is well to drop into second gear to negotiate a blind right-hand sweep, which should be taken with care, accompanied by a violent horn obligato to warn descending traffic.

From the cottage the steady rise to the top gradually opens up one of the finest panoramic views in Devon. Exeter, six miles off, lies 800ft. below, spread out, as it were, for inspection. The river, the Cathedral, and other public buildings can easily be spotted, and Exonians out for a short Sunday morning appetiser are wont to while away the time before descending to Chudleigh to "get the correct time" by endeavouring to locate their respective abodes in the "ever faithful" city.

## A Primitive Telegraphy System and a Duel.

Telegraph Hill derives its name from the fact that it was the site of one of the towers set up on eminences in 1806, at a distance of about ten miles apart, for a system of signalling from the Admiralty to Plymouth. In its original form the apparatus used consisted of six shutters pivoted in two frames, and

Powderham church, surrounded by the exceptionally fine yews, which are worthy of note. In the foreground are three Enfield and two A.J.S. outfits.

by opening and closing them a combination of some sixty words, or groups of letters, could be signalled. The signallers were provided with telescopes. A despatch of ordinary length from Plymouth to London took about seventy minutes to transmit, which in those days was considered something of a feat. Apart from fine scenery, the only thing the "Top of Haldon" can boast of is a racecourse, said to be the most elevated and picturesque in England.

It was near this spot that the last duel in England is said to have been fought in 1823 by two Exeter gallants. As usual, the *casus belli* was one of the fair sex. The grave of the one who did not participate in the coffee can be viewed in St. Sidwell's Church, Exeter. At Chudleigh, the next village, is the seat of Lord Clifford of Chudleigh, surrounded by a well wooded park. There are also some interesting caves here and some eleventh century remains of a palace of a former bishop of Exeter.

At Chudleigh Knighton we branch to the right for Bovey Tracey, two miles further on. The fifteenth century church of Bovey, built, it is said, by William de Tracey in expiation of the part he took in the murder of Thomas à Becket, contains a fine screen with painted figures and a pre-Reformation lectern which, during the Commonwealth period, was buried on the heath to save it from Fairfax's iconoclastic troops who were busy in the district. The Dolphin Inn, in the centre of the town, is associated with the story of the surprising of the King's troops on December 26th, 1645. The Royalists suspected no danger. A quiet game of cards was in progress when suddenly Cromwell and his men appeared under the windows. The officers pitched the stakes out of the window and escaped by the back door while the troops were busy with the scramble.

Bovey is at the foot of one of the Moor's ladders; the rise of nearly four miles to Haytor (1,491ft. above sea level) is continuous, and in places severe. As the top of the hill is approached there will be noticed on the right the remains of the stone lines of the "Granite Railway," by which the granite quarried at Haytor for the building of London Bridge was con-

**Dartmoor as a Touring Ground.—**

veyed to Bovey." Haytor is the best known of the Dartmoor crests, and can be distinguished from all parts of the county. Near by is the modern Haytor Rock Hotel. Those in quest of a more modest "pub" should enquire for the picturesque village of Haytor Vale, which is hidden at the back of the hill a few hundred yards off, and is approached by a steep rough lane entered through an iron gate erected to prevent the semi-wild moorland ponies and other cattle from straying into the cultivated lands. The descent to the Haytor Rock Hotel is quite safe if taken in low gear.

**The Art of Opening Gates.**

Leaving Haytor Rock we pass through what the moor people call "White Gate," shown on the map as Hemsworthy Gate. We feel quite sure that it is only necessary to mention that the many gates which abound on the moor are maintained for the purpose of keeping cattle within certain limits to secure the farmers from the

and many of the congregation injured. The monument of Roger Hill, who was killed, can be seen in the church, while another man who escaped death is recorded to have received such a dose of electricity that it melted the money in his pocket. Readers of "Christowell" will doubtless remember that Blackmore refers to this notable storm. Near the church are some picturesque sixteenth century almshouses.

Half a mile behind the church is the hamlet of Venton, where, sprouting out from a picturesque and glorified wayside farmhouse, is a Roman Catholic

- (1) The picturesque Dartmoor village of Widdecombe.
- (2) Typical Dartmoor. Semi-wild ponies midst a desolate-looking scene.
- (3) Dartmoor rocks, showing effect of weathering.

annoyance and trouble which neglected gates cause them. Some of the gates swing to and fro without fastening; these can, after a little practice, be opened with the aid of the front wheel and a walking stick manipulated from the sidecar, but it requires some dexterity, and is accompanied by a certain amount of risk.

After having carefully closed the White Gate proceed straight ahead down a really steep hill into Widdecombe-in-the-Moor, the church tower of which will have already been observed. This church, which is unusually spacious for a village, is known as the Cathedral of the Moor. An interesting but somewhat "tall" tale, which is set out in verse painted on boards fixed in the church porch, relates to a violent thunderstorm which broke over the district on a Sunday in October, 1638. The church tower was struck

Chapel. The altar light is always burning, and strangers who enter are never interrupted. It is odd to come across such a building in the heart of Dartmoor. The owner of the chapel lives in the adjoining house, and is the authoress of one of the two most interesting of modern Dartmoor novels—"The Heart of the Moor," which presents a most beautiful and vivid picture of all that is best on the moor both in the way of people and scenery. The other book which we have in mind is "My Lady of the Moor," by John Oxenham, in which the principal character is the writer of the "Heart of the Moor." This lady is certainly a most interesting study, as those who have read her book entitled "Answered Prayers" must have realised.

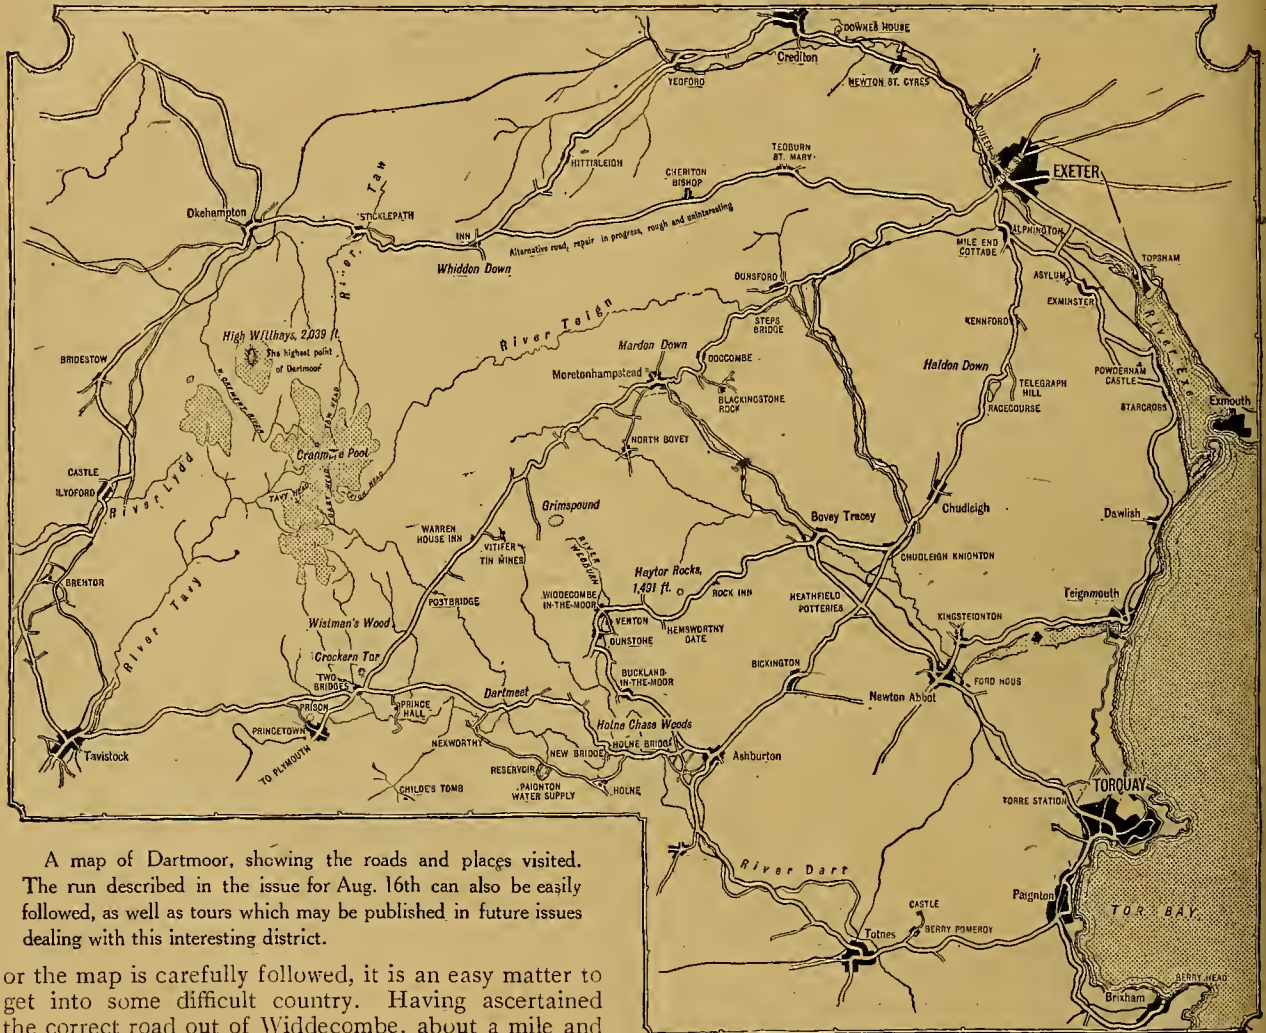

### Dartmoor as a Touring Ground —

Near by at Dunstone is a large block of granite showing several depressions in its surface, worn away, it is said, as the result of the ancient custom observed every five years by the manor tenants—commoners as they are called—placing their "head" rents thereon when they became due. From Widdecombe we make our way to Buckland-in-the-Moor, a veritable paradise of sylvan scenery. The journey from Widdecombe to Buckland is through rough and narrow Devonshire lanes of rather a complicated character. Unless explicit directions are obtained at Widdecombe,

to Exeter (twenty-three miles along the main road), thus picking up his outward trail at Chudleigh. If, however, the day is young and the flesh willing, we advise turning right on reaching the main road from Buckland. On reaching the fork, about two and a half miles on, keep left; the river which bubbles along on the right is the romantic Dart, the lower reaches of which, between Totnes and Dartmouth, are often referred to as the English Rhine.

Nearly six miles on we run into, shortly after crossing the G.W.R. line, the historic pre-conquest town of Totnes. Enter the narrow and busy main street

A map of Dartmoor, showing the roads and places visited. The run described in the issue for Aug. 16th can also be easily followed, as well as tours which may be published in future issues dealing with this interesting district.

or the map is carefully followed, it is an easy matter to get into some difficult country. Having ascertained the correct road out of Widdecombe, about a mile and a half on, take the second turn on the left—practically a right angle turn—and a mile further on be careful not to run past the Buckland Road which turns away sharply on the right. Follow the road straight through Buckland, leaving the church, which contains a Norman font, and the beautiful Holne Chase woods on the right. About three miles on take the tight-hand road of the fork and continue to the main Ashburton-Plymouth road, which is joined about two miles on the Plymouth side of Ashburton.

At this stage the tourist should consult his watch, and passenger, to decide whether he will return to Exeter by turning left and so back through Ashburton

with caution, and turn first to the right to inspect the Guildhall, which was formerly part of the Priory of St. Mary, but has been used for municipal purposes since 1553.

The parish church adjoining was built about 1430.

The street is here spanned by a chamber over the old East Gate which pierced the ancient walls, portions of which still remain, together with the ruins of the Castle. Proceeding in the opposite direction down the main street note the many fine old houses with overhanging gables, and in several instances with upper storeys projecting across the footpath. The River

**Dartmoor as a Touring Ground.—**

Dart is crossed by a noble old bridge, from and below which in the grounds of the Seymour Hotel an excellent view of the river scenery is obtainable.

From this point down to the sea at Paignton is a pleasant and easy run of six miles. Near Paignton is the famous fishing town of Brixham, which has been aptly described as a "Devonshire Wapping with a Billingsgate smell." It was here that William of Orange, who was proclaimed as the deliverer of England from the tyranny of Roman Catholicism, landed in 1688.

From Paignton we proceed along the coast to Torquay (two miles), past the remains of Torre Abbey, built in 1196 by William Brewer for Premonstratensian Canons, of which order Welbeck Abbey was the chief house in England. Follow the tramlines along the front and overlooking Tor Bay out of Torquay to Torre Station, and proceed to Newton Abbot—the New Town of the Abbot of Torre—seven miles off, and select the picturesque coast road to Teignmouth (six miles), thence on to Dawlish (three miles), and so to Starcross, situated on the western bank of the estuary of the Exe. The steep hairpin rise out of Dawlish, on the right of the garage, should be taken in low gear with great care until the right-hand turn at the top is safely negotiated. From Starcross select the road through Powderham Park and past the castle

of the Earl of Devon. On emerging from the park turn right for Exminster. On the left, a short distance out of the village, will be noted the handsome iron gates at the entrance to the grounds of the County Lunatic Asylum.

**The First Volunteers.**

It was a former medical superintendent of this institution—Sir Thomas Bucknell, father of the late Mr. Justice Bucknell—who conceived the idea, which in 1852 resulted in the formation at Exeter of the premier corps of the Volunteer Army, which Lord Haldane's territorial system abolished only a few years ago. The first turn on the right past the asylum is taken, and the River Exe crossed by Countess Weir Bridge. It is interesting to note that at this point the river, the canal (the oldest in England, having been cut in 1563), and the G.W.R. main line all follow parallel courses, passing through a typical specimen of Devonshire pastoral scenery. We next strike the Exeter to Topsham Road, turn left, and enter the city through the site of the South Gate, over which in the bad old days was the debtor's prison which Howard, the prison reformer, described as the most loathsome place in England. For diversity of scenery and interest this tour is unsurpassed in a total distance of about sixty-five miles, and we strongly advise those who can stand a long day to rise early and undertake it in its entirety.

**THE SIDECAR TO THE RESCUE.**

At many camps lorries are forbidden to enter owing to the damage they do to the roads. They are in consequence unloaded at the entrance, and frequently a long wait is the result. On a recent Sunday afternoon one of the canteens was without bread, and the photographer's Matchless was utilised and loaded up with forty loaves and run up to the canteen.

## WHICH TYPE OF SOLO MOUNT?

THE conversation had wound its course through the initial channels with unusual politeness, when suddenly the Journalist observed: "The point of discussion is this—Which type of machine do you prefer for solo use, the V twin, the flat twin, or the single? Also, what do you consider the most comfortable power for touring?"

"Oh, dry up," implored the D.R. "We have already had single *versus* twin and all sorts of things. Besides, why discuss a matter which must be obvious to everyone? Who wants an unbalanced V twin or a thumping single when the perfectly balanced flat twin is a practical proposition?"

"I do, for one," asserted the Manufacturer.

"And I for another," added the Novice. "According to 'Wharfedale,' no suitable frame has yet been devised for the flat twin, while, according to 'Ixon,' it eats up sparking plugs galore. 'Chinook' seems to experience fun with the oiling, and 'Road Rider' complains about the 'what d'you call its.' All this seems to point in the direction of the flat twin still being an expert's machine, whereas the V has been thoroughly tried, and has proved itself in public contest."

"Plug troubles and 'what d'you call its' are not inherent to the flat twin," argued the D.R. "Those allude to were probably overhead valve high speed machines, and you get plug and valve troubles with any engine of that type, whether flat or V or single. I fail to see why a low compression side-by-side valve flat twin should be any more trouble than an ordinary V."

"Well, you can have your multi-cylinder machines," put in the Manufacturer. "Personally, I haven't the time nor the inclination to fiddle with them. Give me the no-trouble single."

"My ideal," said the Novice, "is the 4 h.p. V twin on the lines of the A.J.S. for solo use, or possibly something a little smaller."

### The Small Twin and Reliability.

The D.R. said that he thought small V twins were the most unreliable and undependable little blighters on the road. He could never understand why. "They will suddenly develop some peculiarity which all the king's horses and all the king's men—Unaccountably they cure themselves, go like blazes for a time, then go on the blink again. No, above all things, save me from the small V twin."

"I have ridden one daily, winter and summer, for nearly four years," put in

the Journalist, "and have never had a moment's trouble with it."

"You're the only man yet who hasn't named his preference," the Novice pointed out. "What machine would you choose as an ideal solo mount? The Manufacturer goes for the conventional single, the D.R. for the flat twin not under 3½ h.p., I plump for the 4 h.p. V twin. What's yours?"

"Try an N.S.U. with a dash of vodka!" suggested the D.R.

But the Journalist was busy eating plums, and the matter required some thought. "I think I should bid for the 7-9 h.p. twin with a decent kick starter."

"Then you won't get anything with a decent kick starter from the States," observed the D.R., drily.

"Suppose we each put forward our special reasons for our choice," suggested the Novice. "Let the Manufacturer have first say. Why does he pick the single?"

### Single *versus* Big Twin.

"For the same reason that the Journalist picks a single when it comes to the A.C.U. Six Day or the Scottish Reliability, and he has to get through with his copy," came the prompt retort. "That's why! Because it does a maximum amount of work at a minimum of attention. Because you can neglect it at busy times without permanently injuring it. Because it maintains its tune without constant petty adjustment, and because it is the most economical machine on the road. That's why!"

"What time have I," he added, warming up, "to go fiddling with your petty-fogging little twins in these days of shell production? I want a machine which I know will start second kick when I leave the office late at night, and which I can start out on to go to Birmingham next morning without fiddling with my tappets or taking out my sparking plugs before starting. It's all rot to talk about the flat twin superseding the single! Take my word for it, the single will live on if only because it is a hard-working and honest proposition, fast enough for anyone, and not unreasonable as regards comfort. As a business mount it has no equal."

His vehemence for a moment silenced his listeners. Then the Journalist dropped a plum stone in the wastepaper basket and sniffed. "I don't know that I should choose a single for trial work to-day," he observed coolly. "I should be sorely tempted to choose something on the lines of the four-speed 90° P. and M."

"Why?" snapped the Manufacturer.

"Because it would go through the trial with infinitely less labour, and so would maintain its tune better. In addition to this it would be much less tiring to ride, capable of maintaining much higher speeds over long stretches without exertion, and would finish the trial without the necessity for a thorough overhaul before the next. I have reduced the valves of a single to absolute clinker in a one day trial, and at the end of the Six the whole engine is a physical wreck."

"But," argued the Manufacturer, "how many times have you seen those big twins fail on the test hills, simply on account of their huge weight resulting in wheel spin? How many times have you smiled at their exhausted riders, and thanked your lucky star you were on a comparative lightweight in the form of a reliability single?"

"And how many times have I cursed my single when the big twin men have swooped by me, making up time—when I have seen them ticking smoothly along the difficult patches, knowing that what they lost on the swings they could make up on the roundabouts? As regards weight, the 7-9 h.p. T.T. Indian is little heavier than a Triumph."

"No, but it jolly well would be by the time you had rendered it comfortably fit for competition work by adding a kick starter, lamps, and gear box. You can't compare a stripped machine with one in competition order."

### The Weight Question.

"That's true," agreed the Journalist, "but recent American records prove my point. Our peace-time competitions are purely endurance tests, and could any single on earth do what the Americans have recently done on their big engines? No, the engine couldn't do it, and the rider could not stick it. You cannot overwork and overdrive a machine without overworking and overdriving yourself, therefore a big reserve of power is the chief thing for comfort in an endurance test."

"Comfort!" sneered the Manufacturer. "Who can sanely describe it as comfort to be inflicted with one of these unwieldy camels as a solo mount? The average man does not wish to have to cart a superfluous bulk of weight and machinery about with him."

"No," replied the Journalist, "because the average man does not realise the wonderful docility and numerous other advantages of the big twin. In my opinion it is far better adapted as an old man's mount than the spluttering, high compression little two-stroke. It is a

**The Critics.—**

Rolls-Royce as compared with a single De Dion. It will tick over in traffic like a sewing machine; it will run slowly up hill and pick up at the merest touch of the throttle without resort to the gear change. It is a model of docility and easy driving, and—here is my point—the big twin, not the single, is truly the no-trouble machine! Because it is never overworked it requires no attention, and whereas your single requires decarbonising every 2,000 miles at the outside, the big twin will run for an indefinite period without taking down. That is one reason why the Americans stick to it—because the ordinary Yankee rider will not trouble to decarbonise his engine at regular periods."

**A Founder of History.**

There was a moment's pause. "You chaps have had your say—now let me have mine," suggested the D.R., with an airy wave of the hand. "The Novice can keep his till last. We reserve him as a kind of dramatic adjunct. Well now, I have tried your singles and your big twins. I do not despise either of them. The single has stood by me as a faithful friend in the hour of direst need—such need as I hope never again to experience. I have seen my own life-blood collect on the top of the tank, and mix with the petrol which squirted with every thump from the vent hole. I have clung to its bars when it was a labour—positively a labour—to push open the throttle, and I have sat in the saddle and eaten food, and fallen asleep in the act of raising the food to my mouth. More than all this, I have seen what none of you have ever seen. I have seen a strong man, a bosom pal, embrace his machine in the best way one can embrace a motor cycle, and blubber over it like a kiddy blubbering over his dog, because that machine had stood by him

faithfully as the best of dogs when all human help was beyond his reach. The single has done in history what no other machine can ever do, and because it has brought me, against overwhelming odds, through trial and hardship beyond belief, it would be disloyal to cry it down. But"—and the D.R.'s boyishness returned as though two decades were suddenly lifted from his shoulders—"I cannot help but think that, except as a commercial machine, the fate of the single is sealed. It will live on till the flat twin has attained a degree of reliability equal to the single, then, despite what it has done in history, what it has done for the world, it must die. In one we have the unbalanced engine, which inevitably has its 'period'; in the other we have perfect symmetry, perfect balance, and a machine which cannot help but appeal to the engineering mind as a superior article. The difficulties of housing it, lubrication, the sparking plug problem, will all die in time. That is why I think the unbalanced single and the V twin will live merely till the flat twin is developed. The V twin particularly is a compromise—a makeshift. And I tell you this, that in the next T.T. the flat twin will fairly buzz the speeds up. Now, Novice, what's your say?"

But though the D.R. had returned to his old cheery style, somehow it did not ring true. The Novice had much to say. He preferred the 4 h.p. twin because it was free from the peculiar troubles of the small twin, and for the reasons which the Journalist had outlined as appertaining to the 7-9 h.p. V, without the huge weight of the latter. It could take a sidecar comfortably. It was ideal for solo use. He regarded it as a temperate measure for the moderately temperate man.

A strange quietude fell. At length the D.R. rose, and said he thought he would go, and as his hand fell upon the table

they saw that he was wearing what he seldom wore—a single gold stripe. And, as he left them, each fell thoughtful. This man, the light-hearted, the forgetful, the whimsical, the jester—the man who made foolery of their petty troubles in life—had seen more and suffered more than they had ever realised was within the limits of human endurance.

"Poor boy," said the Manufacturer at length. He, the apparently mercenary, the rough-spoken, the unsympathetic, was the first to break the silence which signified their sympathy. He looked towards the Journalist. "He lost some good pals," he observed, "but I hoped he was beginning to forget."

**The Manufacturer as a Philanthropist.**

The Journalist shook his head. "There are things a man cannot forget," he said, quietly. "Have another drink?"

But the Manufacturer had risen. "No thanks; I'm going home."

And that night the Manufacturer did what he seldom did. He went home by back alleys, and on the way a woman, carrying a bundle—a woman who was ragged, but who muttered something about "soldier's widow"—plucked at his sleeve. He elbowed her roughly aside, then he paused, looked back guiltily, but saw no one was about. He thrust something into the woman's hand and strode on—a crumpled note, but perhaps a human life.

"God bless you, sir. Ga—if you ain't a toff—!"

"Get away from me, woman! It's a lie! You are not a soldier's widow."

The Manufacturer strode on through the gloomy alleyways, his eyes downcast, but as he went he wondered. "If she isn't an honest woman, why was she so ragged—her child so plump? A soldier's widow, and here, by Gad, am I, making shells by the thousand, and for every other shell—a soldier's widow!"

**THE DUCO VALVE SPRING COMPRESSOR.**

**T**HOUGH we have previously illustrated this little tool in *The Motor Cycle*, we do not think that it has yet been realised that it has more uses than that of a valve spring compressor. Since its introduction its inventors have discovered that it can be used for bringing the ends of a chain together, and may also be utilised as a patch compressor. Two plates provided with slot attachments are now supplied (and used in the manner shown in the accompany-

ing illustration) by means of which a patch, after it has been applied to a tube, may be compressed and held in position until the solution has absolutely set.

As a valve spring compressor it is of the greatest use. To employ it the valve cap should be removed and a nut placed in the top of the valve. Then the valve cap should be screwed down finger-tight, so that it presses on the nut. If the valve spring compressor be then placed in position and the handle turned the spring and its cap will be raised, thus leaving the cotter free of access.

**NOVEL CARBURETTER FOR FLAT TWINS.**

**T**HE design of carburetter here shown is the patented invention of a reader, who claims that it offers several unique advantages—slow running, economy, and rapid acceleration being among the foremost. It will be seen that the design is very simple, the jet being screwed into the tie-piece in somewhat the same manner as in the Indian carburetter, while the throttle piston occupies an unusual position at the junction of the

pipes. In this position the slide would undoubtedly be subject to more wear than in the usual position, and a worn slide thus placed would tend to upset the equality of the charges to the respective cylinders, but the possibility of such weaknesses could probably be allowed for in the construction.

The adjustable air port is contained in the barrel directly above the throttle slide, the air supply being admitted through the hollow throttle piston, thus meeting the atomised charge at high velocity and assisting in the direction of complete carburation. An ordinary float chamber is, of course, used, and the carburetter presents a very neat and compact exterior.

A patented design of carburetter for a flat twin engine.

The Duco valve spring compressor.

# THE NEW IMPERIAL MILITARY MODEL.

An 8 h.p. Sidecar Machine, built to the Specification of the Russian Government.

It has already been stated in these columns that some hundreds of machines, built in this country for the Russian Government, have been left on the hands of their manufacturers, and will probably be disposed of to private purchasers as circumstances permit. Among these is the 8 h.p. (twin J.A.P.) New Imperial, which conforms to the essential features of the Russian W.O. specification, as already referred to in our descriptions of other machines built to this order.

Though hardly ideal for solo use in this country on account of their rather high saddle position, brought about by the 28in. wheels and abnormally liberal ground clearance, these Russian machines leave little to be desired for sidecar use, possessing, as they do, several features which are highly desirable in a sidecar machine. Their totally enclosed all chain drive, h.b.c. clutch, ample power, and general solidity of construction are all points the sidecarist desires, while the mudguarding on the Russian machines is generally in the direction of an improvement.

## The Gear Box Unit.

Apart from the general design of the machine, perhaps the chief point of interest in the military model New Imperial is the transmission, for here a very wide margin of efficiency in the way of strength and durability is made. Exceptionally heavy chains ( $\frac{5}{16}$ in.  $\times$   $\frac{3}{16}$ in. front,  $\frac{3}{16}$ in.  $\times$   $\frac{7}{16}$ in. back) are used, thus ensuring long life and freedom from breakage.

The gear box, with the clutch and shock absorber, is made in the New Imperial works. The clutch is a particularly good and thoughtful piece of work, its design being as follows: It is of the dry plate variety, containing three cork plates and four metal of wide diameter. Square corks are used instead of round, it having been found that they are easier to fix in an efficient manner. The gripping surface afforded is abnormal, there being two rows of insets to

The 8 h.p. New Imperial military sidecar. Note the wide magneto shield, also the simple straight rod controls.

each plate, though in practice the clutch has been found to be more than equal to its work with only the outer ring of insets.

Tension is obtained by means of six coil springs mounted on slotted screws in the same manner as in the Sturmey-Archer clutch, but provision is made to assure the continued working of the clutch should the insets be burnt out by mishandling. The springs give the correct tension with the screws turned home, but at the end of each screw, and mounted on the thread, is an extension collar—a small round nut, as it were—which prevents the screw from entering for the full length of its thread the member tapped to receive it. Should the insets be burnt out or excessively worn, the screws are taken out and the small extension collars removed, thus permitting the screws to go further home, and increasing the pressure on the springs, and thereby bringing the metal surfaces of the plates together, so that one is independent of the insets. It would not, of course, be advisable to use the clutch for any length of time in this condition, though the adjustment serves to tide one over till the insets can be renewed. The plates are held in position by means of a large split ring, which can very readily be re-

moved, leaving the clutch mechanism *in situ*.

## The Transmission Shock-absorbing Device.

The shock absorber is contained in the countershaft sprocket, which receives the drive from the engine. The toothed portion of the sprocket is mounted on a large ball bearing, and contains a series of circular rubber blocks. On either side of the toothed member, and fitting closely up to it, are plates, and between these two plates, and passing through the centres of the rubber blocks in the toothed member, are steel pins. The drive, then, is conveyed to the loose portion of the sprocket, which is free to move on its ball bearings, and is communicated by it through the rubber blocks to the steel pins, and thus to the outer plates, which are mounted on the load shaft of the gear box. The shock absorber is of very ample size, and the makers claim its shock absorbing properties to be highly efficient, while undoubtedly it occupies a good position.

The kick starter follows conventional lines, its mechanism being totally enclosed, and the gear change is by dogs on top and bottom and inter-meshing pinions on middle. It is a curious fact that the engagement of the pinions is an even simpler matter than the engagement of the dogs.

A B. and B. carburetter and Dixie magneto are fitted, the latter being

New Imperial gear box. Dog clutches are employed for the engagement of the top and bottom gears, and inter-meshing pinions for the middle gear

### The New Imperial Military Model.—

effectively sheltered from mud and wet by a wide curved sneid, which almost completely envelops it.

The wheel bearings on this machine are a fine piece of work, being of large diameter, and provided with efficient mud and water-excluding felt washers.

The shock absorber. The outside disc is insulated from the toothed portion of the sprocket by means of rubber blocks, through which the drive passes.

The oil pipe is arranged from the B. and L. drip so that, when dripping normally, the feed goes to the front cylinder, but if the pump be used the overflow is fed to the crank case in the

ordinary way, thus providing the main bearings, etc., with a deluge of cold oil.

The back carrier is so arranged that, by depressing a spring bolt, which affords it means of attachment to the saddle stay, it can be swung bodily backwards as shown in the illustration, thus leaving the tyre more accessible for repairs.

The chain cases are up to the usual standard of machines specially fitted with such in compliance with this order. They are reasonably simple to remove, and do not interfere materially with the accessibility of the rear wheel.

As regards general accessibility, this big engine has, of course, to be dropped bodily from the frame for decarbonisation, but this can be done by merely disconnecting the exhaust pipes, etc., and removing the engine plate bolts, leaving the footrests and most other fittings undisturbed. As regards chain adjustment, the gear box is self-aligning, and the four nuts holding it easily get-at-able. Accessibility generally appears to have been studied with care, and in the way of a heavyweight for sidecar use the machine would appear a thoroughly sound proposition.

### Sidecar Connection.

The control is good, the handle-bar clutch being extremely light, and a very simple, but highly efficient, rear wheel brake operating inside a brake drum is used. It will be observed that *straight* rod controls, having the very simplest of connections, are used for the rear brake and gear box, which is an excellent point.

No brazed couplings on the front down tube are provided for sidecar connection, the designer believing that nicety of adjustment necessary for the permanent attachment of a sidecar cannot be achieved when no choice is given as to exact position of the couplings. This, he holds, is particularly the case when machines are sent Overseas. Here some make of

Rear view of machine, showing how the carrier can be swung backwards on depressing the spring lock to facilitate tyre repair.

sidecar never intended to accompany the machine is often attached, and the brazed lugs being *not quite* where they should be, the attachment is never entirely satisfactory.

The sidecar is a good piece of work, with ample carrying room and extremely comfortable, while the outfit throughout is of great strength, though not unreasonably heavy, and should prove to be exceedingly durable.

## MORE EARLY SPRING FRAMES.

Among the Pioneers of Spring Frame Practice was the Bat Manufacturing Co.

An early spring frame machine produced by the Bat Manufacturing Co.

One of three motor cycles built in 1906 by H. Monk, having sprung frames.

IN our issue of August 30th, under the heading "An Early Spring Frame," we published a short description and illustration of a spring frame design of many years ago. The frame of the machine was strongly reminiscent of Bat design, and was sent to us as an experimental Bat, the standard model spring frame of which is well known to every motor cyclist.

The Bat system of suspension, by which the rider is insulated from road shock by means of a saddle and footrests sprung in unison on the rigid frame, has stood the test of many years, though, of course, it falls short of the true spring frame in that only the rider derives the benefit of the springing, the engine,

etc., being carried as unsprung weight.

The illustration on the left is of one of the very earliest spring frame Bats, which made its appearance even before an efficient system of front wheel springing was arrived at. It will be noticed that, though the saddle and footrests are sprung, the front forks are rigid, while the position occupied by the rider is hardly an enviable one.

### An Early Rear Sprung Twin.

The spring frame illustrated on the right was made and invented by Mr. H. Monk, of Waltham Abbey, who writes us as follows concerning it: "It was made during the winter of 1906. The first one was just being finished when

I saw the one you illustrated a week or two ago, and noticed the various points of likeness to my own. This consisted of a double frame, having two springs on each side; the saddle pillar was extended so as to slide in the loop on the top of the loose frame to stiffen it. I built only three of these, but they were in every way satisfactory, and I often wish I had time to build myself one now. So far from being subject to side-slip, they were very free from it, due, I believe, to the fact that the wheel did not leave the surface on a bumpy road. I may say that all of them were used with a flexible Montgomery sidecar. I still have one of the old back frames hanging up in my workshop as a curiosity."

## TIMES TO LIGHT LAMPS.

SUMMER TIME.		
Sept. 13th	...	7.50 p.m.
" 15th	...	7.45 "
GREENWICH TIME.		
Sept. 17th	...	6.41 p.m.
" 19th	...	6.36 "

## Noisy Machines Overseas.

We are informed that the Sydney police have been given instructions to take special notice of noisy motor cycles. Riders of machines which are not efficiently silenced are to be prosecuted.

## What it feels like to own a Motor Cycle.

The American author of an article entitled "Why I am a Motor Cyclist" opens the ball by saying, "Owning a motor cycle is like living most everywhere at once."

## C.O.B.E.

Mr. H. Tempest Vane, who was mentioned in *The Motor Cycle* of August 30th as a Commander of the Order of the British Empire, is general manager and joint managing director of Messrs. D. Napier and Son, Ltd., 14, New Burlington Street, London, W.

## Controlling the Petrol Supplies.

It is interesting to note that, while the Food Controller does his best to control the price of food and maintain supplies, the Petrol Controller apparently views the increase of price with absolute indifference. The cause of the increase is said to be due to the heavy cost of ocean transportation consequent upon the great increase in the rates charged under the Government war risks insurance scheme, but, as pointed out by the Editor of *The Light Car*, the increased insurance rates do not justify the rise. On a cargo of one and a half million gallons an increase of 8½d. per gallon is equal to well over £50,000!

## A Novel Punishment.

Recently a motor cyclist named Andrew Myer was summoned at Los Angeles for exceeding the speed limit. We think that most of our readers are aware that offending motor cyclists are not caught in short-distance traps as in England, but are chased by motor cyclist police, who note that the offender is breaking the law by their speedometers. When Myers was ordered to stop he gave the policeman a chase over the most dusty thoroughfares he could find. Instead of imposing a fine the Judge sentenced Myer to gaol, with instructions that he should be put to work cleaning the motor cycles of the city motor cycle police squad.

## American Motor Cycles.

The American War Department recently bought 5,000 machines. They have now decided to standardise military models as regards their control, equipment, and in certain details of construction, and 40,000 of these are, we understand, to be ordered.

## B.S.A. War Fund.

The balance sheet of the B.S.A. Employees' War Fund, which is just to hand, shows the contributions of the workpeople, staff, and officials together to be £23,358, with the bank interest and the interest on investments the amount is £23,807. The grants to dependants and donations to various war funds have reached the sum of £16,527, the balance being invested in the War Loan.

## Hull Magistrates and Signalling.

The Hull magistrates dismissed a summons against Fred Wm. Young, a fish merchant, who was summoned for not obeying the signal of a police officer on point duty whilst riding his motor cycle. The chairman, Major Barton, said there ought to be a universal system of signalling; they did not consider the way the constable had signalled was right. The signal would have deceived him (the magistrate), and he thought he should have taken exactly the same course as the defendant did. He should strongly urge that the police on point duty should be instructed in

## SPECIAL FEATURES.

### ROTARY AND MOTOR CYCLE ENGINES. NEW IMPERIAL MILITARY MODEL. COOLING AND LUBRICATION.

future when they wanted to stop anyone to put one hand up above the head, and not as in the case before them, where the constable had held his arm out level with his shoulder. They thought the motor cyclist would have stopped if he knew the constable's signal, and they did not think defendant was to blame in the course he took. Defendant, who was legally represented, stated that the officer had his right hand out pointing down Anlaby Road, into which he was going to turn. A motor van nearly ran him down, and it was a wonder he was not killed. He was going to make a complaint to the police authorities.

## The Inventor of the Bicycle.

It is worthy of mention, since the pedal cycle is the father of the motor cycle, that on August 1st the Germans celebrated the 100th anniversary of the birth of the "inventor of the bicycle," Baron von Drais. But it happens that the bicycle was not a German invention at all. A velocipede was invented by Blanchard and Magunier in 1779, while the first idea of a bicycle seems to have occurred to another Frenchman, de Sivrac, in 1690.

## CONTRASTS IN LOCOMOTION.

Pillion riding on a blinkered ass has its charms, no doubt, and if the youngsters had their choice of the sidecar or the ass, it is probable that they would plump for the latter every time, especially if equipped with a good ash stick—but every man to his taste. No doubt the Enfield rider prefers his mount.

### An Opportunity Missed.

*Punch* says: "A man named Kite told the Willesden magistrate that he had joined the Royal Flying Corps, and the magistrates refrained from being funny."

### The National Relief Funds.

At the week-end the principal war relief funds stood as follow:

The National Relief Fund (distributed £3,657,622) .. ..	£6,227,539	0	0
British Red Cross Fund .. ..	7,259,880	0	0
Tobacco Fund .. ..	136,636	0	0

### A Conference of the Military and Motor Cycle Manufacturers in U.S.A.

At a conference of manufacturers and Army officers, held at Washington recently, arrangements were made which enabled the Government to have the immediate aid of expert motor cycle mechanics, in order that the full efficiency of the motor cycle may be made available in the war from the very start.

General Baker at the meeting said it was the experience of our English and French Allies, whereas they bought any and all makes of motor cycles at the beginning of the war, they eventually reduced their selection of solo mounts to two or three different makes, and induced the manufacturers to standardise these, to a certain extent, making the running of bicycle parts interchangeable.

In some respects General Baker was right, but the bicycle parts of these machines were not interchangeable.

### Petrol 25s. per Gallon.

All motor cyclists in this country are grumbling at paying 4s. 3d. per gallon for petrol. It may be consoling to some to learn that in Holland the precious fluid is considered cheap at 25s. per gallon, so a correspondent to *The Times* asserts. Even paraffin has risen to the abnormal price of 10s. per gallon in that country.

### Handle-bar Supports.

We notice that the latest racing Indians are provided with handle-bar supports, consisting of straight tubes running from the ends of the handle-bars to the front axle spindle nuts. This is interesting, as we have not seen the like since the early French racing machines, some of 16 and 20 h.p., used on Canning Town track in 1903.

### Men Wanted for the R.F.C.

The R.F.C. are seeking skilled and unskilled men for their various branches. Men over age are eligible, and interesting employment is offered at special rates of pay. Application should be made at the nearest Recruiting Office.

### For How Much Longer?

In Devonshire recently, the absence of motor cycles in busy seaside resorts, such as Torquay and Paignton, was most marked; the number seen in the course of a day could be counted on both hands. The riders were principally military or naval officers.

### Watch your Head.

The majority of amateur riders do not realise the importance of keeping the steering head bearings in adjustment. Hundreds of machines are ridden with slack steering heads, with the consequence that the steering soon becomes imperfect, and an increased tendency towards sideslip results.

The ball races of a steering head are subjected to side strain in addition to direct thrust, and if they are slackly adjusted considerable wear falls on the sides of the cones, causing them to wear oval. In these days of pot-hole roads this adjustment should be given special attention.

### THE 1920 HIGHWAY ROBBER.

When coal gas supersedes the "juice."

### Overheard in the Garage.

Proprietor: "Jones, petrol is up again to-day."

Jones (the shopman): "Yes, sir. What may the price be now?"

Proprietor: "Well, you had better call it 5s., as that will save altering it again next week!"

### Lighter Four-wheelers.

Our contemporary *The Light Car* this week devotes an article by a well-known engineer and designer to the subject of intelligent weight reduction in light car construction. The "Lighter Light Car" campaign has been running for some months by our sister journal, and doubtless it will tend towards the production of a desirable intermediary between the light car and the heavy sidecar outfit of to-day.

### Another "Hot Stuff" Machine.

For advertising for sale a 33 h.p. Centaur motor cycle, the *Surrey Comet* takes the biscuit.

### An Up-to-date Grocer.

A grocer of Moira, Leicestershire, was recently fined £1 ls. at Coalville for not having proper lights on his motor cycle. He is reported to have offered a bribe of 2½ lb. of sugar to the policeman who stopped him.

### Lucky Farmers.

A contractor complains that farmers in his district have petrol to spare, while he, on whom the farmers are depending for the maintenance and repair of their property, is allowed only a miserable two gallons per month!

We are not keen on airing the views of people who emphasise the injustice of the world by pointing to others more favourably placed; and if the farmers are able to get petrol, then—lucky farmers! We doubt whether our contractor friend would obtain any more if the farmers' supply were cut down—as he suggests it should be—and, anyway, the matter rests in the hands of the Board of Trade.

### Carroll's Average was 53.6 Miles per Hour.

In setting his world's records for 500 and 1,000 miles, for twelve and twenty-four hours, with a sidecar at the Cincinnati, O., Speedway, on August 14th-15th, "Teddy" Carroll averaged 53.6 miles per hour for the entire twenty-four hours of riding, and not 48.28 as originally stated. Carroll covered 1,275½ miles during the entire period of twenty-four hours. He drove a stock Powerplus Indian sidecar outfit.

### American Motor Cycle Recruits.

Glancing the other day through our American contemporary, *Motor Cycling and Bicycling*, we noticed that two pages were devoted to recruiting. This is reminiscent of *The Motor Cycle* in 1915 and 1916, when it was successful in obtaining so many thousands of recruits for the technical branches

of the Army. This department, entitled "Uncle Sam's Fighting Men," will, so our contemporary states, form a regular feature of the paper.

### Chain Cases Wanted.

Why do the makers of chain-cum-belt machines pay so little attention to the adequate enclosing of the front chain? An oiltight front chain cover is more vitally necessary with this type of transmission than with an open rear chain drive, for oil is invariably thrown from the front chain on to the belt, causing excessive slip and wear of the latter. Usually the front chain is fed with lubricant from the crank case release, which is somewhat impartial in its manner of distribution, and it is for the protection of the belt that the totally enclosed front chain is so highly desirable.

# COOLING AND LUBRICATION.

Over-cooling and its Results, together with Notes on Piston Design and Lubrication.

**T**HERE is no doubt whatever that the term "radiation" is wrongly applied in the case of a motor cycle engine. The cylinders are kept cool not by radiation, but by impingement of the air on the cylinder fins. The theory, if such it may be termed, has already been aired in *The Motor Cycle*, and any reader who cares to provide himself with proof can do so by means of a very simple experiment. Place the machine, with the engine at its normal running temperature, in some position where no draught can play upon the cylinders, and it will be found that, even at the end of an hour or more, so slow has been the loss by radiation that the fins are still considerably above atmospheric temperature, whereas, had the machine been left out in the street where some little current of air could impinge upon the fins, it would be stone cold, or almost so, even at the end of a few minutes.

Vast strides are being made in the matter of radiation, but it is to be observed that these experiments are mostly in connection with *stationary* air-cooled engines used for marine work and such purposes. In the case of a stationary engine cooling can truly be said to be by radiation only, and what I am trying to get at is this, that an engine that will run at a desirable temperature on full load in a closed atmosphere for long periods at a stretch, as can the latest A.B.C., would probably run too cool when subjected to a strong blast of air; in other words, if radiation alone will keep it at its best working temperature, radiation combined with violent impingement of the air will probably keep it at a temperature below that at which it works best.

## Loss by Over-cooling.

Car owners know the curse of the engine having a super-efficient cooling system—the engine that does not settle down to its work until it has done ten miles or so—and all manner of devices, such as a clutch for the fan, are in use to cut short the warming-up period. Motor cyclists also are troubled with over-cooling. We all know that an engine runs more economically during the second twenty miles of a ride than it does during the first twenty miles; we all know how extravagant in oil and petrol a machine proves when it is used only for short runs, during which it does not have time to warm up properly. I have myself possessed single-cylinder machines which I used to ride on bottom gear up a steep mountain byroad for fully a mile, joining the main road further on, when setting out on a long ride. That was the only way to warm

up the engine in anything like reasonable time: while I have known other riders who made a practice, in the days of plenty, of allowing the engine to tick over on the stand for ten minutes or more while they donned their overalls and so forth.

Personally, I have never been troubled with over-heating since 1913 or thereabouts, and I think that if cylinders were scientifically designed to avoid distortion, the present-day engine in proper tune would run normally at its best temperature. If we are to have an engine which simply cannot be made to over-heat, even though one overload it by attaching a sidecar and driving badly, then that engine will, when judiciously treated and well handled, probably run at a temperature below its best working temperature, and so will not be efficient. What I mean is that by adopting the steel cylinder we shall have achieved all that can advantageously be achieved in the way of external cooling.

## Smartness and the Power Unit.

It is well to bear in mind that one can have too much of a good thing. For weeks past we have been hammering with fitful energy the matter of improved cooling. We have advocated multitudinous wafer-like steel fins, aluminium pistons, and an engine that is cooled internally by means of a forced draught, but if all these excellent features were carried into practice in their best form the engine evolved would probably put up a very poor show except on the racing track. The internal combustion engine is such a unique compromise—hence its interest—that it is very easy to overdo one's pet theories when carrying them into practice.

Naturally, one advocates the steel cylinder and the aluminium piston, not entirely from a cooling point of view when applied to touring engines, but largely from the point of view of weight. Let us have a slightly more extensive cooling surface, but let the wafer-like fins be crowded round the combustion head and disposed in such a way as to catch the current of air; then let us have the base of the cylinder nicely machined and plated, preferably with copper.

The motor cycle engine of the future, besides being highly efficient, will present a neat and attractive appearance, for every reader is drawn to an engine that looks smart and businesslike on the show stand. How many riders have felt themselves drawn towards the Scott and the Brough on account of the neat appearance of their power units? and I think this matter of external engine finish is one that has been grossly neglected, and that it might advance

Section of piston with cooling fins to relieve the hot spot by means of an air current passing through oiltight ports or breathers in the cylinder walls.

### Cooling and Lubrication.—

tageously occupy a little more thought on the part of designers. Above all things, let us bid farewell to cylinders which rust; let us have plated cylinders in their place, and if a high lustre could be imparted to them it would gladden the heart of many a proud rider.

### A Cool Running Engine which Regularly Overheats.

But to return to the matter of cooling. It is no longer a question as to whether we can efficiently cool the engine externally; the problem lies in distributing the heat evenly, in avoiding hot spots, and in efficiently cooling the engine oil. It would be very easy to arrive at an engine the external cooling of which was so excellent that it could not be made to overheat, yet in other respects the cooling of that engine might be most inefficient, in that if the engine bearings were to last, the unit would demand an excessive quantity of oil. Its external cooling might be superlative; its internal cooling bad.

### Oil Cooling.

It is rather surprising that many leading engineers still cling affectionately to the notion of cooling the engine internally by means of the lubricating oil. We have had it in car practice for years past, and to-day it is cropping up in aero engine practice. Every rider knows that the hottest spot in the whole engine is on the piston head. We have clever little lubricating systems whereby a squirt of oil is shot into the piston, spraying over the hot spot at every stroke. Of course, oil galore is wasted in this way, but that does not matter much in the case of luxurious car and aero engines. Half the oil is flashed into vapour and shot out of the breather, but the greatest shortcoming of the system is that each little squirt of oil must leave behind it a certain deposit which is duly converted into carbon inside the piston, and so in due course the inside of the piston is covered with an excellent non-conducting coat of carbon. For all the good it then does, the squirt of oil might not be delivered at all.

Two features that must be aimed at in the motor cycle engine are low oil consumption and a minimum of carbon deposit. Internal cooling by oil is extravagant and shortens the period between intervals of taking down the engine, besides destroying the lubricating properties of the oil by overheating it. Therefore the idea of oil cooling can be ruled off the boards. What we have to aim at in motor cycle engines is to keep the oil at as low a temperature as possible, so that its maximum lubricating qualities will be retained, and a minimum of wastage will accrue by evaporation, etc.

### Aluminium Pistons.

The aluminium piston of to-day does not make any attempt at absorbing the heat from the hot spot and getting rid of it immediately. This is what should be aimed at. The sole object of the aluminium piston is to conduct the heat from the hot spot and distribute it more or less evenly over the entire area of the piston, getting rid of it in the best way possible by conductivity

through the doubtful medium of the piston rings. This is good as far as it goes. Instead of the piston being red hot at the top and cool around the bottom of the skirt it is more or less of an even temperature all over, so that it does not act as a flash plate for the lubricant; but it relies upon the piston rings for conductivity, and in this respect it falls short of permanency. The piston ring of the future will be extremely narrow—little more than an oil scraper—and so the area of contact will be small. Moreover, if the engine is to be economical in oil and is to require a minimum of decarbonising then the piston rings should be kept as cool as possible, i.e., the heat from the hot spot should be carried away and dissipated ere it reaches the rings.

### The Hot Spot of the Piston.

It is not a difficult matter to evolve an arrangement whereby the heat from the hot spot of the piston is blown into the air and got rid of immediately instead of being carried to the rings. In *The Motor Cycle* of late several ideas have been illustrated whereby the displacement of air in the crank case is utilised to play forcibly on the hot spot (as suggested in "Internal Cooling," issue of April 19th last, page 345), and on this page is illustrated an exceedingly simple method whereby a single port, operated automatically by the piston, brings a cold blast of air in contact with the piston radiating fins at every stroke of the engine.

A baffle would be fitted to prevent oil splashing excessively inside the piston, the gudgeon pin being oiled through the hollow connecting rod.

There are, however, so many ways of cooling the centre of the piston by means of air draught that there is not much object in suggesting more, but it may be added that the only ideas worth carrying into practice are those which are free from gadgets, and which adapt themselves readily to the engine without knocking up the cost, incurring weaknesses, or demanding awkward and unsightly evidence.

### Summary.

The pith of this article is that having apparently mastered the problem of external cooling we need to turn to the problem of getting the last ounce out of the oil used by maintaining it at its maximum lubricating temperature. If this can be done the life of the engine will be indefinite. The best way of keeping the oil at a low temperature is to eliminate that offending hot spot in the piston head, which hitherto has been a veritable thorn in the flesh, and to get rid of the excessive heat by some mechanical means. Taking it that we succeed in this, then we can look forward to an engine that will accumulate a minimum of carbon deposit, and which will possess unlimited wearing qualities, because the short life of engines of to-day is largely due to the fact that their wearing parts are destroyed through the lubricating oil losing its virtues by becoming heated—that is, that half the time the engine is running the oil is at too high a temperature to do its work thoroughly. Cool cylinders alone will not effect this end unless we succeed also in eliminating the hot spot in the centre of the piston or in keeping the oil away from it. CHINOOK.

## MILITARY NOTES.

## MOTOR CYCLIST HONoured—1911 T.T. RECALLED.

MOTOR CYCLIST HONoured  
BY THE KING OF ITALY.

CPL. J. CALDWELL, R.E., has had the bronze Military Medal for valour conferred on him by the King of Italy.

A BRAVE MOTOR CYCLIST  
MARRIED.

A FORTNIGHT ago Capt. Kingston Graham Hodgson, R.A.M.C., was married to Miss Winifred Jenkins at Chertsey. Capt. Hodgson, a 'Varsity man, volunteered for service as a despatch rider at the beginning of the war, and joined the immortal Fourth Division in the retreat from Mons and Le Cateau, and served during the Battle of the Marne. In the course of his service as a motor cyclist he was blown from his machine and wounded, after which he returned to England, qualified as a doctor, and again returned to France.

## THE T.T. OF 1911 RECALLED.

PTE. T. W. VANN, of the A.S.C., sends us the following letter: "I am enclosing a photograph of some of the boys attached to various companies of the M.T. (A.S.C.), Sydenham Centre, which, I believe, will interest a number of readers.

"On looking through the photograph you will note a well-known private owner competition rider (Cpl. F. Johnson, now Sgt.), who rode in both events at the Isle of Man in 1911, and being first private owner home in the Junior on a 2½ h.p. Humber. He also rode a twin Matchless in the Senior, to say nothing of numerous other events both at Brooklands and elsewhere. He is one of the best, and very much liked by all.

"The names of the riders, reading from the left, are: Ptes. T. W. Vann, F. Bolton, J. P. Wilson, — Sharpe, P. Hilton, R. Bott, J. Butcher, L. Walsh, Sgt. F. P. Johnson, Lt. Richards, Ptes. F. J. Chenery, H. G. Hitchcox, E. M. Reynolds, and O. Joyce. Best wishes for the 'Blue 'Un.'"

A ONE-LEGGED MOTOR  
CYCLIST.

WE have received from Bryan Jefferys (formerly of the Border Regt.) a letter which shows that, in spite of the loss of a leg, he still retains his enthusiasm for the motor cycle:

"The enclosed photograph may be of interest in view of the fact that I lost my right leg while serving with the Border Regiment in Flanders. The machine is a three-speed T.T. Norton, and I have nothing but praise for it. A

B. Jefferys, formerly of the Border regiment, with his brother in the sidecar. Jefferys unfortunately lost a leg in the in the early part of the war, but he is still a keen motor cyclist.

distance of over 3,000 miles has been covered without the slightest trouble of any sort, with the exception of one puncture only. The tyres—heavy studded Dunlops—are standing wonderfully well, and although the back tyre studs are getting rather worn after continuous sidecar work, the tyre itself has hundreds of miles to run yet. I could not have a handier or more convenient machine, and it has an extraordinary turn of speed, too, which is very much to my liking, as before the war I was used to riding big solo twins. My passenger is a younger brother, who is now driving one of the Red Cross ambulance cars attached to the French Armies."

## AN ACTOR MOTOR CYCLIST.

CAPTAIN GEOFFREY GWYTHYR, who is now playing "Cosmo" in "Carminetta," after being blown up and buried by a shell in France, was thrown from his motor bicycle while doing staff work in England.

## E.O. COMMISSIONS.

WE understand that in future commissions for the post of equipment officers in the R.F.C. will not be granted until the candidate has completed a course of training as a cadet.

FORMER MEMBER OF THE  
STAFF KILLED.

WE greatly regret to learn of the death during a flying accident of Lt. L. E. Stuart Vaile, which occurred in Norfolk on August 29th. He was a member of the staff of this journal in 1913-14. He was the son of the Rev. A. Vaile, of West House, Seaford. He enlisted in August, 1914, as a despatch rider, and had two and a half years' service. When killed he was acting as instructor, R.F.C.

## AMONG THE EXPERTS.

PRIVATE HANDEL DAVIES, M.T., A.S.C., who has been on active service since 1914, previous to which he was a competition rider, says: "I have met many of the expert men I used to know before the war, viz., Capt. Newsome, Rowlandson, H. Newman, Duggy Brown, and H. R. Davies. I understand the latter is now a prisoner of war. I have also met Capt. Lindsay, R.A.M.C."

U.S. AIR BOARD'S THREAT TO  
SEIZE PRIVATE WORKS.

THE United States Aircraft Board has threatened to seize all the well-known aeroplane manufacturing plants and the works of the makers of aeroplane parts, following an investigation which showed that the Government was being charged excessive rates.

Motor cyclists attached to the various companies of the M.T., A.S.C. Reading from left: Ptes. T. W. Vann, F. Bolton, J. P. Wilson, — Sharpe, P. Hilton, R. Bott, J. Butcher, L. Walsh, Sgt. F. P. Johnson, Lt. Richards, Ptes. F. J. Chenery, H. G. Hitchcox, E. M. Reynolds, O. Joyce.

## LETTERS to the EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

### POLICE INTERFERENCE.

Sir,—In answer to Mr. Alfred E. Skinner regarding being stopped by the St. Helens' police, I may say that I have heard nothing further. Certainly, I have not had occasion to go through St. Helens since, but have ridden round about without being stopped. With regard to his contemplated tour in North Wales, I should think the risk would be infinitesimal, and I should not hesitate to go.

H. ALDRED.

### BROOKLANDS MODELS.

Sir,—With regard to your note *re* Norton Brooklands Specials in your issue of September 6th, as I dismantled, re-assembled, and tuned all these engines, without exception, at Brooklands, I have rather full records regarding them, and shall be very pleased to supply any member of the public, who will send a stamped addressed envelope and quote the number of the particular engine he is interested in, with any details required, including the actual speed done on the official test.

D. R. O'DONOVAN.

### ROAD SIGNS.

Sir,—Being an interested reader of your journal, and associated journal *The Autocar*, I should be pleased if you could find space for the following criticism on the extremely bad method of road signs employed in this country. The familiar red triangle has had its day, and motorists can hardly be expected to observe a sign which one meets every couple of hundred yards. Again, "Dangerous Cross-roads"—surely sufficient warning—is ignored nine cases out of ten, because they are either posted on the main road, where it is the duty of the rider on byroads to take special care, or where there are no cross-roads, as three places I could mention have but a lane running in. Can anyone ask main road users to look at every gap in the hedge when two hundred miles has to be completed in a day? May I just draw the attention of motor cyclists to the danger of Bagden Hill, near Burford Bridge, where, fortunately, I escaped with my life and my friend's by doing the right thing at the right moment? At the top there are two signs—the familiar red triangle and "Dangerous bend." Why not put "Six dangerous bends—gradient 1 in 3½," which might have saved a young fellow killed there recently?

Earlswood.

NEARLY DONE IN.

### HANDLE-BARS.

Sir,—May I venture an opinion on the subject of handle-bars? I have possessed, in succession, a 1912 Scott, with high narrow V shaped bars and long footboards sprung at both ends; a 1916 3 h.p. Enfield, with semi-T.T. bars and footboards sprung one end; and a 1915 T.T. Norton, with full T.T. bars and footrests in a line with the saddle. I have several times done the same seventy-five miles run on each machine non-stop. In each case I have run to a schedule giving 26 m.p.h., so I have a good basis for comparison. On the Scott I got backache, and found the saddle uncomfortable. This discomfort disappeared on the Enfield, but I found after about sixty miles my legs always ached intolerably. On the Norton I am free of all aches, except on a long down grade, e.g., Birdlip, when the weight on the arms is distinctly noticeable.

The Norton has the same saddle as the Scott, so that I conclude that the saddle "hardness" is not the fault of the saddle, but of the upright position. The leg ache on the Enfield I put down to the combination of semi-T.T. bars and footboards, for when the body leans forward and the foot is kept flat, the leg muscles below the knee are con-

tinually in tension. On the Norton the legs are apparently more cramped, but as the footrests allow the toes, so to speak, to hang down there is no strain on the leg muscles.

My conclusion then is that while footboards are comfortable enough with touring bars, rests are far preferable with T.T. or semi-T.T. bars. I think this possibly explains the shape of bars used by Baker and Parkhurst, as their machines both have footboards, though a reference to the photographs (August 16th and September 6th issues) show that "Novice" was not quite accurate in calling them touring bars, as in the one case the ends of the bars are level with the saddle, and in the other considerably below it. For short, dry runs touring bars are delightful, but for long, non-stop runs, or in grease, that full T.T. bars are infinitely more comfortable is my experience.

J. M. PHILPOTT.

### A PUZZLING TROUBLE.

Sir,—I wish to relate a trouble I had lately with my two-speed motor cycle, thinking it might be of some help to fellow motor cyclists. The other day I was out for a jaunt, my machine going very well: it got up a fair gradient beautifully on high speed, but further on I had to throttle down on a slope on account of the bad state of the surface. A little further on, as the road became better, I opened the throttle, but the machine did not pick up. Finally I had to run on low gear, and had some difficulty in going up a slight hill, when the engine stopped altogether, and I set to work to investigate.

Finding that the front cylinder was not so hot as the back one, I thought something was wrong with the ignition, so setting the engine in motion I tried the front sparking plug, but I found that it was sparking beautifully, and the back one was all right, so it did not seem that the ignition was at fault. I looked at the carburettor for obstructions, but everything seemed in good order; then I tried to restart the machine, which ran beautifully as far as my friend's house. When I left him the same trouble began again for a while, but at last the engine fired on both cylinders. I went to see another friend a few miles further on without any trouble, got up another steep hill fairly well on high, and rode home at good speed. When in the town I had to throttle down again on account of the crowded traffic, but was only able to reach home on one cylinder, as the front one would not fire.

The following day I put the machine on the stand and tried to locate the trouble. I tried the magneto, the high-tension wire, the sparking plug (the spark was very good), then both valves and springs, then the carburettor, pipes, and connections, but all were in good order. For the first time I felt very much puzzled. As the magneto was giving a good spark at both plugs, evidently the trouble was not there, but, everything having been looked at except the carbon brushes, I decided to unscrew the front one, and on looking at it and examining it carefully I found that the brush was sticking slightly in the holder, and when pushed as far as it would go it would stay there. No doubt this was my trouble, and on dismantling the brush and its spring I found that some of the coils were working over the others, so that it was not doing its work. When running the engine fast the spark was strong enough to jump the gap, but when running slowly it was not jumping at all, and this was the reason why my machine would only fire properly at high speed. So ended a trouble which seemed very puzzling. The machine now goes as well as ever.

GEO. G. BELLNOT.

Tours, France.

## WHICH TYPE OF ENGINE?

Sir,—I see under the above heading that "Qui Vive" makes a few remarks on a new type of engine. By a new type is meant something new to the public. No doubt the few remarks made on this subject will whet the appetite of a number of your readers for more. In the first place, experimenters on such an engine have been going on here in England for years, but naturally obstacles have turned up thick and fast. Compression gave a lot of trouble; also something was required to act as a carburetter; also the great quantity of heat developed was too useful to throw away by air or water-cooling methods. I have reason to believe that the public will have to wait, perhaps, a year or two before this engine is brought to a commercial success, therefore to give more than a bare outline is impossible. The engine to which I refer was originally intended for aeroplane work, the latest model is capable of four power strokes per revolution—the earlier models had two; also it is valveless. Perhaps it will be fitted up with spark plugs; if so the number will be four. It is intended to run in either direction. Water is as necessary for satisfactory running as petrol, and is injected at a certain period, so I should say that the hotter it gets, in reason, the better, as it will then use more water and less petrol. The cylinder is of steel, with cast iron liners, and it has positive scavenging. British manufacturers will get going, but first require something worth the trouble and capital. The reason the public have not heard about this before is because it is only in its experimental stages, and development takes time. We are, I think, much nearer the internal combustion turbine now than four months ago.

V. MITCHELL.

## THE ADVANTAGES OF A WATER DRIP.

Sir,—Perhaps an account of some additions I made to my motor cycle might be of interest to readers.

I am a general practitioner, and use my machine daily in all weathers.

Extra springing and silencer.

It is a 1917  $\frac{3}{4}$  h.p. Ariel with a not-too-heavy sidecar. I have nothing but praise for the outfit (usual disclaimer, please!). Even in the coldest weather of this year it rarely failed to start first kick after standing all night in the garage (unheated).

On straight runs, with passenger, I get 65 to 75 m.p.g. I completed 100 miles in 5h. 5m.

The additions were as follow:

(1.) Terry's spring links (6 h.p. pattern), which are a wonderful comfort, combined with the spring seat-pillar.

(2.) Tension springs across the chord of the sidecar C springs. These make the riding of the sidecar much more comfortable.

(3.) An extra silencer was made for me by a local tinsmith at a cost of 5s. 6d. It fits over the tail pipe, is 12in. long x 3in. diameter, with a baffle plate on the inner sleeve

Hot air intake.

over the tail pipe, and a final exit some 4in. long. This, with light springs holding the tappets up to the valves, makes very quiet running for a single.

(4.) A hot air intake to the Amac carburetter (I use a 30 jet with war spirit). It is of brass tube, fitting over the

air intake. The cylinder end of this tube is cut with an H-shaped slot, and the flanges turned out and fitting between the fins on the cylinder between the valves.

(5.) A water drip and extra air fitment. I made a small "tank" out of a Shinio tin, and a sight drip feed out of a glass and vulcanite syringe and a hypodermic needle. This is attached to the mechanical horn by two Meccano strips bolted to the fore plate of the horn. From the drip feed a tube goes to a two-way tap from an old surgical aspirator, which is screwed into a block of wood clamped under the horn. This tap is then carried down to a piece of tubing screwed into a hole drilled in the carburetter intake, between the throttle barrel and the cylinder stub pipe, by means of flexible gas tubing. The tap gives extra air by the

The arrangement of the water drip.

forward end of the cross tube, normal carburetter action when shut off, and a water drip by the rear end of the cross tube.

The hot air intake and the extra air have added some 10 to 15 m.p.g. I have run on paraffin with a little ether added in an emergency.

The water drip reduces knocking on hills in a marvellous way. The engine will pull up long gradients that meant a lower gear formerly. When the drip is "on" the exhaust becomes much softer in tone, and the drive less inclined to be snatchy. It does not increase power, and necessitates reduced air intake when in use. I believe it keeps the engine decidedly cooler. I average somewhere about 100 miles per week, and have now had the machine for seven months.

Let me add that, during a long period of trench life (as a battalion M.O.) last year, your paper was a brilliant spot in a mud-coloured existence, and much that I gleaned therefrom has been of great service to me in my present somewhat disabled condition.

M.R.C.S.

Bolton.

## STARTING WITHOUT RAISING EXHAUST VALVE.

Sir,—One of the most awkward mishaps to a motor cyclist on the road is to break the control wire of his exhaust lifter. If on the move, he cannot stop unless his throttle will close right over, and many will not. If standing, he cannot start. We all know the old device of the penny with a hole in it and a string. I have never tried it, and fancy it would be of doubtful utility. But I have discovered that it is quite easy to start an engine without ever touching the exhaust lifter, and think the tip may be worth communicating. It has relieved me of the fear I have always had of being hung up on the road by the exhaust lifter cable breaking.

Work the kick starter till you are up against the compression. Now open the compression tap, and press on kick starter pedal till air ceases to issue from tap. Release pedal. The piston is now at the top of the compression stroke. Inject a few drops of petrol, and close compression tap. Now give kick starter pedal a vigorous shove, and engine will fire at once. Controls are, of course, in the usual position for starting—air closed, throttle partly open, and spark slightly advanced.

The idea occurred to me, on reading E. Hardman's letter in *The Motor Cycle* of August 30th, page 216, that by using the compression tap to release compression, instead of the exhaust valve, one would be independent of the latter, and its being temporarily out of action would not matter. By using the clutch and throttle when changing gear, one would then be entirely independent of the exhaust valve, and the breakage of its control would not matter in the least. The plan is completely successful. WM. F. A. ELLISON.

[This is often the easiest way to start a single-cylinder machine.—Ed.]

### INVERTED CONTROL LEVERS.

Sir,—There is something to be said in favour of these from the "Is it safe?" point of view. In case of a spill they do not damage one's person, while the other kind are capable of inflicting an awful gash in the leg or knee. I have actually seen this happen.  
Coventry.

INVER.

### BRAKES.

Sir,—I have just read with interest the discussion on "Brakes" in your issue of August 30th. The subject interests me, as I was recently fined 10s. for driving without a front brake. I had only removed the blocks a day or two before, as it was impossible to adjust the brake to avoid rubbing. It may interest Devonshire readers to know that there is a policeman specially placed in Exeter to look at the brakes of passing motor cyclists.  
T.E.H.  
Havant.

Sir,—*Apropos* "The Critics," my Harley-Davidson combination has only one brake fitted. I find the engine acts well enough down any hill when running on low gear with exhaust valves lifted; but were the chains to break, I am afraid the band brake would not be sufficient on a steep hill. Can any reader suggest a suitable brake for the front wheel, which, by the way, is a disc wheel? This does not allow much room for the brake blocks, and I think a brake on the front wheel advisable in the case of a combination.  
T. BARKER.

### DECARBONISING.

Sir,—As the originator of the oxygen process for decarbonising cylinders, I venture to point out that the popular misunderstanding in regard to this method finds its way into print in your issue of August 30th, page 215. The "oxygen flame" is there spoken of, whereas it should always be remembered that oxygen is only a *supporter of combustion*. It is the carbon that burns, entering into combination with the oxygen and forming carbon dioxide (CO<sub>2</sub>) and a variable amount, according to conditions, of the very dangerous gas carbon monoxide; most of it, however, being consumed before issuing from the cylinder into the atmosphere.  
GUY S. A. B. S. WATKINS.  
Lieut. R.N.V.R.

### AVERAGE SPEED.

Sir,—I notice in your paper several "tall" claims under this head. Perhaps the following experience of mine, last year about this time, would interest some of your readers. I set out to ride to Paignton *via* Gloucester and Taunton, riding an 8 h.p. 1914 Chater-Lea, with a friend (about eleven stone) in sidecar, in addition to about 1 cwt. of luggage, tools, spares, and a spare tin of petrol. For the first thirty to forty miles as far as Dowlais top, it is all heavy climbing. I spent two and a half hours on the road for food and refills of substitute (I used nothing else), and arrived at Exeter (where my driving chain broke, and where I had to leave the machine over night) at 7 p.m., having done the whole 210 miles or thereabouts in nine hours actual driving, or an average of 23½ m.p.h. I drove the whole distance, but felt the result that night in the wrists and at the back of the neck, otherwise I was quite fit.  
R.H.O.

### THE PETROL POSITION.

Sir,—Your article on the above is good reading. When rumour states there is plenty of petrol, for once it does not lie. Last Tuesday a friend of mine filled up his car at Barnsley, and they told him at the depot they had 16,000 gallons in stock *waiting for customers*. It would be interesting to know why miners are able to purchase new combinations and get permits for petrol, and yet others connected with collieries in official positions and who have owned outfits for years cannot get a renewal. I should be happy and proud to take off my hat to the man who can understand the working of the Petrol Control Committee. It would, I think, have been much better to issue permits on payment of the tax, and leave it to the motorist to get the "juice." If he could not he would lose his 6d. per gallon; if he could it would show there is no shortage. And if there is a shortage why do they allow it to come into

the depots at all; why not keep it where it is wanted? This method might be more of a businesslike way, and we cannot lay the "crime" of business methods against the persons concerned.

The more one learns of the true state of affairs the more disgusted with the meddling one becomes.  
GEO. WESTON.

### BUILT AT THE FRONT.

Sir,—Thinking you may be interested to know what can be done with "bully beef" and biscuit tins, I enclose a photograph of our "Pug," which we built while on active service.

It is composed of the following parts:

A Levis engine, which we found. Frame which was bought as a bargain from a Frenchman for 25 francs. Handle-bars which we took off a push-bicycle and rebent

Motor cycle built on active service from parts collected here and there. (See accompanying letter from Cpls. Cox and Morgan.)

with a pair of wood grip extensions. Tank made out of sheet steel. Mudguards built up from biscuit tins. The fittings, such as foot brake, footrests, engine plates, and magneto control, etc. (with the exception of nuts and bolts and wire control, which we begged off the Signals) we made from raw material. The bicycle has done 3,000 miles, is still going strong, and will climb any average hill. I may say we have since fitted spring forks and two-speed gear, which we took off a captured Hun N.S.U.

SEC.-CPL. J. R. COX.  
L.-CPL. W. G. MORGAN.

### ALUMINIUM AND AIR COOLING.

Sir,—I have been much interested in the discussion, the use of aluminium as a radiating agent in motor cycles, which has been taking place in your paper lately. One point has struck me: all seem to have used *polished* aluminium fins or jackets. It is well-known that a dead-black surface radiates far better than polished metal, so I wonder that no one has (apparently) tried dead-black aluminium, which should give even better results than have been accomplished hitherto. Aluminium is easily given a dead-black surface, which, in my opinion, would not detract from the appearance of a cylinder.

The white of a fresh egg is applied by means of a soft rag or rubber sponge (a brush produces bubbles, which appear as light spots later). When a thin, even coating has been applied, the part is baked for some time in a hot oven. (It may be sufficient to paint a cylinder with the egg and run the engine for a time, but I would not like to venture a positive opinion on this point.) A fine dead-black surface should result.

On my present work I cannot try any experiments, but I should be much interested to read of further results in this direction. I see no reason for the trouble and weight of water-cooling.  
L. J. VOSS.

**A Car Licence for Motor Cycle.**

At the beginning of the year 1917 I had an 8 h.p. Humber motor car, for which I took out a three-guinea licence. Now I have sold the car and bought a motor cycle. Shall I have to take out a Revenue licence for this machine, or does the three-guinea licence cover it?—A.W.

As you have sold your car, the three-guinea licence in your possession will see you through for the year as duty on the motor cycle.

**Irregular Firing.**

(1.) The back cylinder of my 1913 twin Rex is constantly oiled up, and the excess oil gets out of the cylinder bases between the washers, but the front one is dry and does not show any signs of overoiling. Would you give me a hint as to the cause of this? My machine has an oil pipe from the crank case to the induction pipe. (2.) On starting, both cylinders fire, but when I engage the clutch one will stop firing, with the result that if I have a passenger on board the engine stops. If I run for a while on the one cylinder the other will start firing after about 300 yards. If I lift the exhaust lever very carefully I can often get them both firing regularly, when I ease the compression a little. I have the same difficulty sometimes after about ten miles running, and if I get off, pump in about three pumpfuls of oil, and start, I run all right again, but the same thing will occur after another ten or fifteen miles. My machine has drip feed lubrication, as well as the hand pump. (3.) Should I pump oil in as well as use the drip feed, and, if so, how often? I do not mix my lubricating oil with petrol on account of the pipe from the crank case. (4.) If I put extra washers under the cylinder caps would that assist me? I think I must have too high compression. I am running on 75% paraffin, with a 28 jet in a B. and B. carburetter. This is set between the cylinders. I have a fine copper gauze in the induction pipe to assist in breaking up the fuel. I have tried with a file to find which cylinder is the culprit, but sometimes it is the back and sometimes the front.—H.C.

(1.) This seems to show that you are using too much oil, which you have to do to get a sufficient supply for the front cylinder. The remedy would be to connect your drip feed to the front cylinder and allow the back cylinder to be oiled by splash. You could then use your hand pump when the engine seemed to be at all short of lubricant. (2.) The trouble in question may be due to an air leak at the induction pipe union to the cylinder which misfires. Look to your contact breaker, see that the points separate properly, and try a new plug in the back cylinder. Also note that the plug gap is correct. (3.) Use the pump only when you think the engine is short of oil, or when you desire to give extra oil, such as when on a hill. (4.) As you are using a good deal of paraffin perhaps it might be desirable to reduce the compression in the manner

suggested in your letter. We are not sure that a fine gauze in the induction pipe would be of any great advantage. You should also look to the strength of your exhaust springs, and overhaul the engine generally.

**Knowledge of the Use of Tools.**

Under the heading "Touring Outfit," every edition of "Motor Cycles and How to Manage Them" includes a small hand vice. I have been a motor cyclist for seven years and have never been able to think of a single use to which this tool could be put; what is it for? I have questioned my friends, also motor cyclists of long standing, and they say they only carry one because, according to the handbook, it seems to be the proper thing to do.—E.W.H.

One useful purpose to which a hand vice might be put would be in the case of a nut or washer, or any small part which required to be filed. This work could not possibly be done without a hand vice, as something is required to hold so small an article. In the case of some part requiring to be compressed, which offered greater resistance than could be overcome with a pair of pliers, there, again, a hand vice would be very useful. We have carried one for many years, and, although we have not had to use it very often, when it has been wanted it has been wanted very badly.

**Knocking.**

I have a 1913 three-speed clutch model Triumph, and have had the engine down, fitted a new piston and rings, and new bushes in the connecting rod. It has made a great improvement in power, but the engine knocks very badly on hills and when I slow down for corners; also it gets hot after a very short run of about eight miles, the crank case included, as I cannot hold my hand on it. I have timed the spark with the lever fully retarded, the piston on the top of the stroke, and the points just breaking. Is this correct? When I lift the exhaust there are two or three loud explosions in the silencer. What is the cause of this?—F.J.M.

The ignition is certainly timed a little early. It would be better to time it in this way, but with the spark two-thirds retarded. The cause of knocking may be due to too weak a mixture. Try closing the air when you wish to accelerate after slowing down; also retard the spark. The engine may improve a little after the new portions have become run in. The cause of the explosions in the silencer is that unburnt gas passes into it, and with the valve raised this is ignited along the exhaust pipe by the spark from the plug.

On page 239, col. 2, one line from the bottom, "eighty-five" should read "two hundred and fifty."

**EXPERIENCE WANTED.**

"T.R.F." (London). — Henderson, general reliability.

**READERS' REPLIES.**

**A Mysterious Noise.**

With reference to the above (August 30th, page 216) in a 1915 Scott, if your correspondent will carefully check the timing he will find the metallic clank he speaks of disappear. Also allow me to state that when a Scott is properly timed it is almost impossible to make the water boil. Mine will rev. for hours with a loaded sidecar without boiling.—1915 SCOTTIE.

**Difficult Starting.**

In connection with the question by "Leo" in *The Motor Cycle*, August 30th, on difficult starting, perhaps my experience would be of some help. My machine is a 1914 4½ h.p. L.M.C., three-speed hub and clutch, with hand or kick starter, and fitted with Bosch magneto. Up to this spring I have always had a difficulty in starting, and, in fact, latterly it was a perfect nightmare to me. The engine would not start at all with handle, and only after great difficulty by pushing; sometimes I had to run with it for a considerable distance, and just when I felt absolutely exhausted it would fire, and run O.K. afterwards. Last April I gave the engine a good clean, in preparation for this season, but the engine refused to fire, although with a plug on the outside of the cylinder it sparked all right. I tested the timing of valves and magneto, cleaned Senspray thoroughly, jet included, bound all connections with tape, held cloth over air intake, cleaned carbon brush, and took magneto off machine, cleaned it as well as I could, and warmed it up in the oven, but all to no avail. I laboured the whole of one Sunday, and was absolutely disgusted when I examined the high-tension wire connection at plug end and found that the wire was only connected up with half the strands. I cut this half off and connected up with the whole of the wire, put plug into cylinder, and turned the handle, and to my pleasant astonishment this solved the problem, as I have had no trouble since, starting easily with handle or push off at walking pace. Have you ever heard of such a case?—A. A. MURRAY.  
[We have not.—Ed.]

### Variable Pulley Gearing.

The drawing illustrates a countershaft gear, in which the final drive is by means of a V belt running on variable pulleys. The construction is such that all the pulley flanges are moved simultaneously, so as to maintain a true belt line, whilst the operating mechanism is enclosed. A is a tubular countershaft driven by chain, gearing from the engine. Upon the countershaft are slidably mounted the pulley flanges B, C, and these are connected by dowel pins D to liners within the countershaft, which in turn are connected to sleeve nuts E, engaging a screwed sleeve mounted on the fixed

spindle F. This sleeve is provided with an operating lever G, and the two screw threads are of opposite sense, so that rotation of the sleeve moves the sleeve nuts and pulley flanges in opposite directions. Equivalent mechanism is provided to actuate the rear pulley flanges H, J, except that the sense of the threads is reversed, so that as the front pulley is opened out the rear flanges are closed. The operating lever K for the rear pulley is coupled up to the lever G, so that the two act in unison. The rear pulley is carried upon a sleeve mounted upon a fixed spindle, and the wheel is rotatable upon the sleeve, but may be coupled thereto by the cone clutch mechanism L. It will thus be seen that operation of the pulleys provides a gradually variable ratio, and a true belt line is maintained. At the same time

the tension of the belt may be caused to remain constant by suitably proportioning the screw threads operating the relative pulleys.—A. H. Johnson and L. Holmes, No. 107,504.

### A Saddle Improvement.

The perspective drawing given illustrates a simple and ingenious method of supporting the peak of the saddle so that it is free to yield vertically. Extending from the rear of the saddle to the forward end is a leaf spring A, which may be laminated if preferred. This spring is secured to the seat proper by studs B,

and is given an upward set, so that it tends to support the seat in a horizontal position, but is free to yield under shocks. The saddle frame is substantially of ordinary construction, but it will be seen that a strengthening bar C runs from the forward end of the frame to the rear.—R. W. Smith, No. 108,053.

### An Improved Belt Fastener.

It is an advantage with belt drive to reduce as far as possible the gap which exists between the ends, and the construction of the belt fastener illustrated produces this effect in a novel and ingenious manner. One illustration shows the belt fastener assembled, whilst the details are shown separated in the other views. It will be seen that the fastener comprises two end pieces A, and these are connected by means of a pair of plates B, each plate being formed at one end with a key-hole slot C, and at the other end with a peg D. By bringing the peg on one plate in line with the enlarged part of the slot on the other plate the plates may be caused to engage, the end pieces A first having been brought into position upon the pegs. The sides of the plates are

provided with facings to engage the pulley, and the effect is to produce a belt fastener, the centre part of which can be brought to the same section as the belt, so that in effect two very slight gaps only are required between the belt ends.—S. T. Robson, No. 106,445.

## SPARKLETS

### British Magnetos.

We are in receipt of a well-illustrated and attractive booklet, entitled "M-L All-British Magnetos." The pamphlet consists chiefly of a description of one of the biggest magneto works in this country.

### Old-time Cyclists.

The annual dinner of the Fellowship of Old-time Cyclists—which now numbers nearly four hundred members—will be held at the Connaught Rooms, Gt. Queen Street, London, W.C., on the evening of Wednesday, October 17th. The hon. sec. is Mr. W. J. Harvey, Holly Lodge, Gunnersbury, W.4, from whom further particulars may be obtained.

### Advance in Price.

The Palmer Tyre, Ltd., inform us that, owing to the increased cost of raw materials, they have been compelled to raise the prices of Palmer motor cycle covers by approximately 15%. There is, however, no increase in the price of Palmer inner tubes.

### Change of Address.

Messrs. Phelon and Moore, Ltd., have moved from their old depôts to larger premises at 4, Berners Street, just off Oxford Street. These constitute one of the largest motor cycle repair shops in London, and after the war showrooms will be established in this building.

### An Echo from the East.

From a far Eastern post comes the following letter from an A.C.U. member, now an officer in the R.F.A.: "As it is most unlikely that I shall be returning to Great Britain before a considerable period of service in the East, I trust that you will accept my resignation from the Auto-Cycle Union. I should like to place on record the fact that during the short time that I was in England the Auto-Cycle Union badge on my machine was responsible for much attention and consideration, both in garages and on the road, which I should not have received had I not been a member (touring) of the Club."

### J.A.P. Booklet.

We are in receipt of the J.A.P. booklet of the 4 and 5 h.p. twin engines, published by Messrs. J. A. Prestwich and Co., Ltd., Northumberland Park, Tottenham, London, N.17. This is a handbook which should be possessed by every J.A.P. owner, as it contains a vast amount of useful information. We are often asked if a certain engine will fit into a particular frame. Should the enquirer wish to fit a J.A.P. engine, if he turns to this booklet he will find all dimensions given, together with lucid diagrams. The whole book is beautifully illustrated with half-tone plates from sketches which have appeared in *The Motor Cycle*.

## THE DUNHILL M.C. JACKET & OVERALLS

AS SUPPLIED TO H.M. GOVERNMENT.

Planned on the saddle, so to speak, the garments combining smartness with perfect ease and freedom.

Made in Lightweight Materials, for Summer riding, and properly ventilated.

The quality is unequalled anywhere for the price.

# MISCELLANEOUS ADVERTISEMENTS.

## PRICES.

**ADVERTISEMENTS** in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to **ILLIFFE & SONS LTD., and crossed**

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

## NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

## DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Illiffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

## SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.
